WASHINGTON, D.C. JANUARY 1972

FOREWORD

The National Environmental Policy Act, signed into law on January 1, 1970, established a national policy to "maintain conditions under which man and nature can exist in productive harmony, and fulfill the social, economic, and other requirements of present and future generations of Americans."

As a step in implementing this policy, the President, with the consent of the Congress, established the Environmental Protection Agency in December of 1970. His stated purpose was to fill the need for "a strong independent agency" to serve as an effective, impartial arbiter of environmental matters, particularly in establishing and enforcing pollution control standards.

But any sound standard-setting and pollution control program must rest on a solid scientific and technical base. This is the reason for the Agency's concern for an effective research program, both internally and in other government and non-government organizations. Much is known about pollutants—their sources, their transport mechanisms, their effects, and control techniques—but much remains to be learned. Meeting these needs depends significantly upon a strong research capability, which must encompass a broad spectrum of disciplines—physical sciences, health sciences, and engineering, as well as the social sciences.

While these endeavors are supported largely by the Federal Government, they are conducted in academic institutions, State and local organizations and laboratories, private foundations, professional associations, and industrial organization, as well as in Federal laboratories. In addition, many foreign institutions contribute to the programs.

Maximizing benefits from the Nation's growing environmental concerns requires developing the full potential of this widely dispersed research capability. Because of the very number and diversity of organizations and activities involved, however, there is a serious hazard of unwitting duplication or gaps in research efforts. Complete information about on-going research and effective information transfer thus become key elements for assuring that individual scientists, engineers, administrators, and policy officials have access to knowledge of "who is doing what, where, and with whose support."

Toward that end, the Environmental Protection Agency is releasing this report: *Environmental Protection Research Catalog*. The 5,488 project descriptions contained herein should assist participants in Government, industry, and universities to select new areas for research, while avoiding wasteful duplication. By identifying individuals and organizations active in the same or closely aligned fields, communication of ideas, opinions, and data should be facilitated. And policy planning and decision making at all levels should be enhanced by the overview this compilation provides of the scope, balance, and texture of environmentally-related research. It also represents a contribution to our growing cooperation with the international agencies concerned with global pollution.

It is hoped that among the benefits from this publication will be expanded recognition of the value of descriptive information about programs, and support for activities designed to improve the flow of information among specialists working in this area. I commend this report to all of those interested in the environmental sciences—in their endeavors to help this Nation achieve the goals of its new environmental ethic.

I wish to express our special appreciation to the staff of the Smithsonian Science Information Exchange for their skilled and prompt performance of the many onerous and difficult details involved in the production of such a publication.

STANLEY M. GREENFIELD, Ph.D.

EDITOR'S NOTE

The Environmental Protection Research Catalog, sponsored by the Office of Research and Monitoring of the U.S. Environmental Protection Agency, has been compiled by the Smithsonian Science Information Exchange, Inc., from its files of ongoing research Notices as of October 1971. Since research grants may have been transferred from one sponsoring agency to another agency or division within the Government, the supporting agency listed reflects the latest information received by SSIE from the supporting organization at the time this catalog was prepared. In addition to Federally supported research, this volume also includes selected research grants sponsored by private foundations, foreign governments, universities, state agencies and individual scientists.

This compilation is not intended as a complete collection of environmental research, but rather as a selection of ongoing research grants concerned primarily with environmental protection, pollution and contamination, and research involving the deleterious impact of man on his environment. Selection of the research Notices included was based on guidelines established by the Environmental Protection Agency with suggestions from the various contributors. Scope notes preceding each sub-chapter are designed as an aid to indicate the subject area included. Many of the research Notices included in any one chapter or sub-chapter may also be appropriate in other chapters; therefore, use of the Subject Index is recommended in locating specific areas of interest.

The Subject Index is based on terminology developed by the Smithsonian Science Information Exchange, Inc. Specific index terms may be arranged in hierarchies indicating relationships between broader and narrower subject terms. Thus, related terms may be grouped together under a more general subject heading (e.g., PESTICIDES: Insecticides, DDT). Each Index Term is followed by the project title, a list of about six descriptors, and the chapter number of the project. Additional cross-reference information may follow an index term where appropriate. For example, projects concerned with thermal pollution are indicated under THERMAL POLLUTION followed by the cross-reference note "—*see* Water Poll.". Additional thermal pollution studies appear under WATER POLLUTION SOURCES. In other cases, general subject areas may be referred to more specific topics (e.g., RADIATIONS—*see* specifics; or COSTS—*see* Economics Entries).

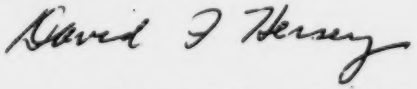
All investigators cited on the source document are included in the Investigator Index. An asterisk is used to designate the individual specified as "principal investigator" on the source document is, in fact, a program manager who is not working at the contractor location given in the project summary.

The Performing Organization Index is an alphabetic listing of the performing organization and its location.

Due to the time of compilation, not all of the entries in the Supporting Agency Index have been updated to reflect transfers of responsibility to the Environmental Protection Agency. All tasks listed as supported by the U.S. Department of the Interior—FWQA are now supported by EPA. Similarly, substantially all the tasks listed as supported by the U.S. Department of Health, Education, and Welfare—P.H.S. are now supported by EPA) Exceptions would be a limited number concerned with health aspects of radiation and a few concerned with occupational health.

All of the indexes in the Catalog were generated by means of a computer, necessitating a limitation of the number of characters available for index terms and captions. In some instances, abbreviations had to be used.

We hope that the users of this Catalog will advise the Smithsonian Science Information Exchange, Inc. of any errors of omission or commission that have been made. Also critiques of this Volume are encouraged so that future editions may best present their information content by means of format and indexes which are convenient and acceptable to the user.



DAVID S. HERSEY, *President*
Smithsonian Science Information Exchange

DESCRIPTION OF RESEARCH TASKS

1. AIR QUALITY

A. EMISSION SOURCES

Research Concerned Principally With Sources of Air Pollution Including Types, Industries, Materials, and Processes.

1.0001, ATMOSPHERIC DIFFUSION OF TOXIC PROPELLANT BY-PRODUCTS

G. MILES, U.S. Natl. Aero. & Space Adm., Marshall Space Flight Center, *Huntsville, Alabama* 35812

The long range objectives of this effort are: To implement atmospheric diffusion models made available under contracts NAS8-30503 and NAS8-24438, which are to predict downwind concentration of toxic type vehicle exhaust by-products during launch activities as associated with skylab and space shuttle type vehicles, and determine atmospheric data input to models; and make any necessary modifications, and verify the diffusion prediction models. The atmospheric diffusion models applicable to the KSC environment will be implemented in FY-71. A contractor, with a fluent understanding of atmospheric diffusion theory and automatic computer systems, will implement the diffusion models. These models apply to contaminates released into the atmosphere at any point from surface to 30KM. Diffusion models will predict downwind estimates of particulate and gaseous materials. Models were tailored to KSC environment in that much of NASA'S 150-meter meteorological tower data and upper atmospheric data for KSC were used to develop necessary parametric input data. The investigator shown above is the Project Monitor whose telephone is 205-453-1120.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

1.0002, ATMOSPHERIC RADIOCHEMISTRY

P.K. KURODA, Univ. of Arkansas, Graduate School, *Fayetteville, Arkansas* 72701 (AT(40-1))

The objective of this research is to learn more about the behavior and movements of radioactive fallout particles in the atmosphere. Radioactive isotopes injected into the atmosphere by the nuclear test explosions can be used as tracers in the studies of the movement of air masses, and also many other meteorological phenomena. The levels of various radioactive isotopes in rain, snow and ground-level air are being measured at Fayetteville (36 degrees N, 94 degrees W), Arkansas; for example, Sr89, Sr90, Ba140, Ce141, Ce144, I131, Be7, Bi210, Pb210. Daily variation of the concentrations of single fallout particles in the ground-level is also being measured. A long-range air trajectory study is also being carried out for the nuclear debris travelling eastward and circling the earth three or four times at 300 mb 500 mb levels.

The mean stratospheric residence time of Sr90 has been calculated to be about 1.0 year from the radiochemical data. The residence time for Ce144 seems to be somewhat shorter (about 0.8 years). The pattern of daily variation of the single fallout particles and fission product concentrations in the ground-level air at Fayetteville, Arkansas can be interpreted in terms of a) the cycling effect of the nuclear debris in the troposphere and b) local meterological conditions.

SUPPORTED BY U.S. Atomic Energy Commission

1.0003, THE VARIOUS POLLUTING SUBSTANCES EMITTED IN DIESEL ENGINE EXHAUST GASES

E. LECLERC, Belg. Ctr. Stud. Docum. Waters, *Liege, Belgium* (2R52065529)

The discharge, nature and concentrations of various polluting substances emitted in the exhaust gases of diesel engines are to be studied.

Document provided to SIE by the Highway Research Information Service.

SUPPORTED BY No Formal Support Reported

1.0004, CHARACTERIZING ASBESTOS-BEARING AEROSOLS

P.K. MUELLER, State Dept. of Pub. Health, *Berkeley, California* 94704

In the first two years of the three-year grant to characterize asbestos-bearing aerosols, we have developed a method for the collection and measurement of asbestiform minerals in air. The means to differentiate asbestos from the many other fibers in air has been accomplished. The method will identify the specific type of mineral fiber composing the various forms of asbestos. Morphology and electron diffraction are used. The method will measure the amount of asbestos by means of electron microscopy according to count and size, and enable a mass calculation from density values. The method yields a true picture of the occurrence fo the fibers relative to their size distribution as found in the air with no alteration of their actual airborne size by sample handling. A filter medium of excellent retention for the fine asbestos fibers has been found. Previously it was believed that chrysotile asbestos would be almost the sole type of mineral fiber found, samples of urban air have shown the presence of amosite asbestos, an amphibole type.

The effort of the first two years has produced a method and data on asbestos concentration in a limited of urban and suburban sites. The proposed work for the third year, now in progress, is to sample other sites, such as downwind from industrial sources. The sampling program has prospects of great production, but the laboratory work is necessarily slow because of the complex and lengthy processes involved in quantitative electron microscopy. We propose to extend the asbestos work for three more years to generate laboratory data and reports from the samples of outdoor air to be taken in the third year of the current funding period. A further extension of sampling is proposed for the continuation period: There may exist an unsuspected and anonymous contamination of the air supply of buildings where asbestos-lined plenum chambers have been installed. We propose to survey public buildings for possible contamination.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0005, COMBUSTION GAS COMPOSITION

E.S. STARKMAN, Univ. of California, School of Engineering, *Berkeley, California* 94720

Research is oriented towards investigation, experimentally and analytically, of the more fundamental aspects of the problems of combustion system derived pollutants. In particular the mode

and character of the formation and production of objectionable exhaust materials is to be investigated. Emphasis is directed towards determination of the mechanisms of formation of air pollution precursors in combustion systems in order to further the basic understanding of the kinetic processes by which the deleterious chemical species are formed.

Species currently being investigated include nitric oxide, carbon monoxide, carbon dioxide, unburned hydrocarbons and the hydroxyl radical. The work is being conducted in internal combustion engines, combustors, and flame systems. Methods of investigation include ultraviolet spectroscopy, nondispersive infrared analysis, ionization flame detection, mass spectrometry, chromatography, digital and analog computer techniques.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0006, AROMATIC BY-PRODUCTS OF COMBUSTION

B.D. TEBBENS, Univ. of California, School of Engineering, *Berkeley, California* 94720

The research during the past year has been a continuation of the study concerned with the fate of airborne polynuclear hydrocarbons. Emphasis is on the reactions occurring on the aerosol carrier, namely, airborne soots. This initiating work on photooxidation of hydrocarbons on airborne soot is being related to published results obtained on the same hydrocarbons subjected to oxidations in the laboratory, but not in the airborne state.

The photooxidations occurring on arborne soot apparently follow to some extent the same pathways as non-photostimulated oxidation as the products are the same, but there is considerable variation in the relative abundance of intermediates and stable end products. Only a portion of the hydrocarbon disappears from the soot particle, the degree being directly related to the surface area exposed to light. The intermediate and end products are oxygenated; however, the photooxidation on soot proceeds very readily in an inert atmosphere. The rate of disappearance of the hydrocarbons is directly related to the intensity of light at wavelengths of maximum absorption. Identified products such as intermediate hydrocarbon diones and relatively stable hydrocarbon diacids account for approximately 25% of the lost hydrocarbons. Numerous unidentified intermediaries are known to be present as indicated by a large number of resolved fluoresce. bands on thin layer chromatogeous.

Continuing work will involve a mass balance of products using labeled hydrocarbons; a more thorough evaluation of surface-volume relationship of soot to hydrocarbon oxidation including the degree of carbon activation, the latter may be the source of oxygen on the oxidation; a more thorough look at the oxidation occurring at zero light intensity (10-15% of hydrocarbon disappears) including the use of admix oxidizing gases; relating the laboratory results to comparable phenomena occurring in the outdoor atmosphere; and improving analytical details.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0007, NUMERICAL MODEL OF THE URBAN ATMOSPHERE

L.O. MYRUP, Univ. of California, School of Agriculture, *Davis, California* 95616

We intend to formulate a working numerical model of the processes by which pollution, heat and moisture change above a city. These processes include the emission, transport, turbulent diffusion, and removal of air pollution; radiational, advective and turbulent transfer of heat: evaporation, condensation and advective and turbulent transfer of water vapor. The initial effort will be directed towards the clear- skies, summertime situation.

The model will be tested against measurements to be made, as part of the project, in the Sacramento Valley of California. In particular, verification data will be obtained for a volume of air above the city of Sacramento and a representative upwind rural site.

We shall investigate the feasibility of operational use of the model in routine meso-scale meteorological and air pollution forecasting. We intend to work in close cooperation with the Secramento office of the U.S. Weather Bureau for this purpose.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0008, HYBRID 14-COMPUTER OPTIMIZATION OF DISTRIBUTED PARAMETER SYSTEMS

W.J. KARPLUS, Univ. of California, School of Engineering, *Los Angeles, California* 90024

This research program is directed toward the application of hybrid computer techniques to the optimization of distributed parameter systems. Utilizing the favorable results obtained in the solution of a difficult identification problem in the ground-water area, work will proceed on the investigation of new optimization algorithms to permit a reliable and effective approach to a suitable mathematical representation of the diffusion field in the urban air pollution problem. Nonlinear dynamic systems and modelling of high-speed ground transportation system will be explored.

A unique algorithm to identify time-space-varying parameters in parabolic and hyperbolic partial differential equations effected a considerable improvement in the identification of parameters; however, it does not provide for a true stochastic approach to the problem of identification from noisy input-output data. This identification problem will be reexamined from the standpoint of communication theory and the theory of prediction and filtering.

Additional work will also be performed in applying the newly developed continuous-space-discrete-time methods to field problems governed by hyperbolic and biharmonic partial differential equations.

SUPPORTED BY U.S. National Science Foundation

1.0009, AIR POLLUTION RESEARCH

R.D. KOPA, Univ. of California, School of Engineering, *Los Angeles, California* 90024

Nitric oxide formation during the combustion process in an internal combustion engine can be considerably affected by the properties of the walls of the combustion chamber. According to Rozlovskii in his comparative study of the works of Zeldovich, Frank-Kamenetskii, and others, the reaction of nitric oxide formation and decomposition proceeds simultaneously by a chain and by a biomolecular mechanism. Because the theoretical yield of nitric oxide by the chain reaction is five to ten times larger than that by the biomolecular reaction, the nitric oxide concentration in engine exhaust gas could be noticeably affected by the specific properties of various wall deposits.

To test this hypothesis, an experimental reaction vessel was designed which permits the investigation of the effects of 1) the properties of wall deposits , 2) the surface to volume ratio, 3) the cooling rate of the combustion products, and 4) the fuel composition on the yield of nitric oxide from the combustion of a premixed fuel- air mixture at constant volume. The composition of the combustion products and the resulting concentration of nitric oxide is determined by means of the Magnetic Mass Spectrometer.

The photochemical reaction between hydrogen peroxide and carbon monoxide at 254 mm and 27 degrees C has been studied. With H2O2 at 1.1 torr and CO in the range 5-25 torr, the reaction produces water, carbon dioxide, and trace amounts of hydrogen. The following chain mechanism yields a kinetic rate expression which is obeyed experimentally: (a) H2O2 plus h nu yields 2 OH (to obtain I sub a); (b) OH plus CO yields CO2 plus H (to obtain K sub 2); (c) H plus H2O2 yields H2O plus OH (to obtain K sub 3); (d) OH plus wall yields wall OH (to obtain K sub 4).

Thus, chains are terminated by attachment of OH to the wall of the quartz reaction vessel. For a CO pressure of 12.7 torr, the quantum yield of CO2 formation is 105. The complete integrated rate expression is: 1/(CO)o-(H2O2)o (log (CO)o-(CO2)/(H2O2)o-(CO)-log (CO)o/(H2O2)o) equals 2 k2/k4 lot. (Although I sub o does not appear in the mechanism and I sub a does, I sub o may be introduced by noting that for weak absorption, our case, I sub a equals I sub o(H2O2).)

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

1.0010, DIFFUSION AND DISPOSAL OF AIR POLLUTION
M. NEIBURGER, Univ. of California, School of Letters, *Los Angeles, California* 90024

The overall objective of this project is the development of a numerical simulation model by which the concentrations of air pollution over an urban area can be computed by computer as a function of space and time, given the distribution of meteorological factors (winds and temperature) and the pollution sources in space and time.

During the first year of our research period, our work has been devoted almost exclusively to resolving some of the fundamental theoretical problems which have heretofore hindered the development of generalized air pollution simulation through models. Some preliminary work is being done on programming and testing these models.

During the coming year we plan to complete the development and testing of the models, and to apply them to progressively more complete computations of the transport, diffusion and reactions of contaminants in the Los Angeles Basin for a variety of meteorological situations.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S

1.0011, LIDAR OBSERVATIONS OF LOWER TROPOSPHERIC AEROSOL DISTRIBUTIONS DURING BOMEX
W.B. JOHNSON, Stanford Research Institute, *Menlo Park, California* 94025 (AT(04-3-115/PA)

The Stanford Research Institute Mark V lidar (laser radar) will be used to measure the aerosol distribution in space and time from an aircraft platform over the sea east of Barbados during the 3rd BOMEX period. The objectives of the program are as follows: a. To measure, by means of an airborne lidar system, the horizontal and vertical variations of aerosol concentration in the lower troposphere in the trade-wind region during BOMEX, and hence to infer the horizontal and vertical variations in atmospheric thermal structure, particularly those in the trade-wind inversion. b. To compare the lidar-obtained total aerosol distributions and inferred thermal structure with independent measurements of Be super 7 concentrations in an effort to discover any significant relationships, including evidence of possible mechanisms of upward or downward mass exchange through the trade-wind inversion. c. To observe the spatial and temporal changes in aerosol concentrations in the regions surrounding typical trade cumulus and active cloud and precipitation areas, in an attempt to determine estimates of the washout and rainout coefficients in the cloud and subcloud layers. d. To delineate, insofar as is possible, the boundaries of the continental dust stream reaching the BOMEX area, and to determine if any evidence exists of increased cloud activity in the vicinity of these streams of potential nucleating particles.

Results: The lidar instrument used a noedymium laser (1.06 mu wavelength) and had a firing rate of approximately one pulse per 3.5 sec. Most of over 5000 lidar signatures collected during eight flight missions were obtained over the eastern portion of the BOMEX area at 10,000 ft and at a speed of 100 m sec-super 1, with the lidar pointing 60 degrees below the horizon.

The data are sufficient to allow presentation of several vertical cross sections of optical density covering 'slices' of the lower atmoshpere 3000 m deep and tens of kilometers long.

The first data analyzed clearly reveal well-defined haze layers associated with the subcloud layer and with the trade-wind inversion. There may be a dust layer above extensive lower clouds. Within cloud layers, clear air between clouds typically gives less signal return, indicating cleaner or drier air. Experimental runs indicate increasing turbidity above the clean layer associated with the trade-wind inversion. (Text abridged)

SUPPORTED BY U.S. Atomic Energy Commission

1.0012, LIDAR STUDY
W.G. JOHNSON, Stanford Research Institute, *Menlo Park, California* 94025

Complete study of plume rise, geometry, dispersion, and particulate concentration distribution of lidar measurements of power plant plumes in western Pennsylvania area. DM will provide meteorological support to contractor's field studies at LAPPES sites.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0013, STUDIES OF NATURAL AND POLLUTANT SOURCES OF CARBON MONOXIDE
R.C. ROBBINS, Stanford Research Institute, *Menlo Park, California* 94025

We have developed a practical concentration and purification system for atmospheric carbon monoxide (CO). This system will now be used to collect one milligram minimum size atmospheric CO samples, oxidized to carbon dioxide (CO sub 2). The CO sub 2 will be collected and stored at liquid nitrogen temperature for carbon isotope ratio analyses. The concentration of CO in air samples will be monitored during CO sample collection wth the SRI-developed CO analyzer. Concurrent concentration measurements of atmospheric carbon dioxide will be made with a Beckman Model 215 nondispersive infrared analyzer. Isotope ratio measurements will be made on both atmospheric CO and CO sub 2. Urban atmospheres normally contain about 1 to 5 ppm of carbon monoxide. This concentration is 10 to 50 times higher than the ambient CO concentration in clean atmospheres. Thus, 90 to 99% of urban CO will be contributed by combustion of fossil fuel and should exhibit a super 12 C-super 13 C isotope ratio similar to that found in direct auto exhaust samples. The isotope ratio measurements on CO sub 2 will also tend to corroborate the degree of pollution by combustion. Samples will also be taken at California coastal areas such as Fort Bragg or Point Reyes.

Two field programs are proposed for remote acquisition of atmospheric samples; Wake Island in the northern hemisphere, and American Samoa in the southern hemisphere. Sites within the trade wind latitudes would ensure collection of a homogeneous sample during the required sample collection interval of three to four hours.

It is expected that this research will provide quantitative data on the contributions of natural CO sources to the total CO found in the atmosphere.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0014, DYNAMICAL MECHANISMS PRODUCING LARGE-SCALE ATMOSPHERIC TRANSPORT OF TRACE SUBSTANCES
J.D. MAHLMAN, U.S. Navy, Postgraduate School, *Monterey, California* 93941 (AT(49-7)3026)

The overall objective is to delineate the important dynamical mechanisms leading to systematic transport of trace substances in the troposphere and stratosphere. The method consists of a number of quantitative diagnoses of various circulation and transport phenomena. These consist of: case studies of surface fallout phenomena, analysis of the mechanics of jet stream maintenance and associated transport implication, numerical diagnostic computation of ozone balances in the stratosphere using the AFCRL 'Ozonesonde Observations over North America', and numerical integration experiments on long-term transport and diffusion of stratospheric trace substances using actual data. This latter approach incorporates separately the effects if sub-grid scale diffusion, large-scale eddies, and the mean meridional circulation. Each of these experimental approaches requires development of separate diagnostic techniques. A necessary condition for success in almost any of these approaches is that the vertical motion field be satisfactorily resolved. As a result, one of the basic endeavors in this project has been to develop acceptable techniques for resolving the vertical motion field.

Results: The most important as yet unpublished results are summarized below. Demonstrated that the net transverse flow about the polar front is thermally direct and completed a study of the energy balance in jet oriented coordinates. Completed initial ozone balance case and demonstrated that large-scale vertical eddy flux is quantitatively important for producing a systematice downward transport of ozone in the lower and middle stratosphere. Completed preliminary numerical integrations of strato-

spheric trace substance transport from arbitrary initial distribution. This showed that the large-sclae quasi- horizontal eddies are capable of effecting a net northward-downward trace substance transport even when such an action is opposed by the mean meridional circulation.

SUPPORTED BY U.S. Atomic Energy Commission

1.0015, CHARACTERIZATION OF SMOKE FROM CELLULOSIC FUELS
E.F. DARLEY, Univ. of California, Air Pollution Research Center, *Riverside, California* 92507

The general objectives of this project are (1) the determination and characterization of the effluents produced in the pyrolysis and combustion of cellulose under different atmospheres, and with differing amounts of inorganic contaminants and (2) the determination of the specific reaction mechanism whereby these effluents are formed--both in pure and in 'treated' cellulose. It has already been established that trace inorganic impurities and slow heating rates can drastically change combustion rates and products formed, even changing an essentially flaming process to a completely glowing one. By preparing specifically- labeled radioactive cellulose and pyrolyzing or combusting it under carefully controlled conditions, the evolved products can be traced to their locations in the origional cellulose, thus helping to establish the mechanism of their formation. Since specifically-labeled cellulose is not available commercially, a major aspect of the current work involves its preparation and the development of techniques and procedures for its assay.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0016, AIR POLLUTION FROM FOREST AND AGRICULTURAL BURNING
E.F. DARLEY, Univ. of California, Air Pollution Research Center, *Riverside, California* 92507

The increasing use of controlled burning of accumulated forest fuels in public and private land is an important factor in reducing fire hazard and maintaining favored plant species. Some forest fuels are treated with fire retardants to reduce the danger of escape from controlled burns. Also considerable amounts of agricultural wastes are burned including brush from rangelands contiguous to forests, grain stubble and fruit orchard prunings. It is important to know the pollutant contributions of such burning. It is therefore the objective of this project to determine the kinds and amounts of gaseous and particulate emissions from various types of open burning. The principal research will be conducted in specialized equipment which simulates open burning. Special attention will be given to burning under varying conditions of composition and moisture, loading, slope, ignition pattern and chemical treatment. Much of the work will be conducted in close cooperation with the U.S. Forest Service Fire Laboratories at Riverside, California, Missoula, Montana, and Macon, Georgia. Where appropriate, results from Grant AP 00568, wherein the chemical process of combustion is being studied with the aim of reducing harmful pollutants, will be applied to the burning situations of the present proposal.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0017, CALIFORNIA ASSEMBLY - STEAM BUS
UNKNOWN, State Assembly, *Sacramento, California* 95814 (000047)

a. To procure and demonstrate four transit buses equiped with external combustion engines in transit operation to substantiate the advantages over internal combustion engines, obtain performance, descriptions, and substantiate the public acceptance of such service. Special advantages claimed are better acceleration, higher speed, absence of noise, fumes and hazardous exhaust emission, and reduced operating costs. b. Report

1.0018, LEAD ISOTOPIC CHEMISTRY FOR POLLUTION RESEARCH
T.J. CHOW, Univ. of California, Graduate School, *San Diego, California* 92038

The objectives of this project are to conduct basic research on the isotopic biogeochemistry of lead, the use of lead isotopes as pollution tracers, the relationship between lead and other constituents in various environments, and the dissipation and removal of lead from the atmosphere.

The trend of lead isotopic variation in potential pollution sources such as gasolone, oil, and gas fuels, coal and industrial chemicals will continue to be monitored. After having established lead isotopic composition in source materials, the lead isotopes in the aerosols, river and harbour waters, municipal reservoirs, industrial wastes, sewage and soil will be determined. By correlating isotopic composition of lead in the source materials and in the environmental pollutants, the transport mechanism of the pollutants will be elucidated. The relationship between lead and silicate, iron, zinc, boron in the atmosphere and rain water will be investigated to determine the effectiveness of the rain as a scrubbing agent to cleanse the atmosphere.

The distribution of lead and other elements in the 'natural' environment will be studied by sampling air and rain water away from continental contamination. This part of the sampling program will be carried out at mid-ocean regions aboard research ships during oceanographic expeditions and on weather ships. The results will establish the 'background level' of lead and other pollutants and will serve as the basis for evaluating the degree of contamination in the urban and industrialized regions.

For long range research, effects of chemical pollutants in the atmosphere, foodstuff and potable liquids will be evaluated by the isotopic technique. Furthermore, the lead and other metallic ions in biological specimens such as plants, animal tissues and body fluids will be investigated.

1.0019, ATMOSPHERIC POLLUTION AND ISLAND OF HEAT
M. PANISSETT, Univ. of Montreal, *Montreal, Quebec, Canada*

No summary has been provided to the Science Information Exchange.

SUPPORTED BY Canadian Government - Ottawa

1.0020, KINETICS OF ASSOCIATION-DISSOCIATION REACTIONS
G. BURNS, Univ. of Toronto, *Toronto, Ontario, Canada* (AF-AFOSR-2016-71)

Technical Objective: AFOSR support of Burns' work has been since 15 Oct. 1963 and jointly with the Defense Research Board of Canada since 1964. The relevance of this chemical research is in furthering our understanding of shock waves such as those created by supersonic missiles. The scientific work in the past has been the study of the dissociation and association of halogens using shock tubes and high temperature flash photolysis apparatus. Study of the chemistry of dissociation association reactions of halogens should give indirectly information on the O2 reactions and thus is of importance both in shock wave studies and the atomic recombinations which occur in the exhausts of rockets. A side issue is the importance of the work in upper atmosphere chemical reactions and pollution.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0021, METEOROLOGY FOR NUCLEAR TESTING
P.W. ALLEN, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302

Provide meteorological support for all nuclear detonations, tests and rocket experiments at the Nevada Test Site. Research into meteorology of diffusion of effluents. Develop instruments, measurement techniques. Develop atmospheric models to predict the transport, diffusion and deposition of nuclear effluents.

Meteorological support of nuclear tests is planned at near the FY- 69 level. Continue study of radionuclide transfer processes. Expand research on problems connected with trajectories and fallout from small cratering and contained industrial applications. Provide complete meteorological support for all programmed experimental plans (detailed weather forecasting and documentation, radiation estimates, climatological support). Evaluation and improvement of models for use in weather, fallout and diffusion predictions.

Prediction estimates of radioactive effluent transport and resulting exposure levels for all underground nuclear explosions and rocket engine tests were used for event scheduling, area clearance and control, and monitoring in off-site areas. Available numerical/statistical prediction techniques involving computers were evaluated. Radar weather surveillance over most of the southwestern states was arranged for evaluating and predicting precipitation as a factor in radioactive cloud tracking and in deposition or rainout. Published and distributed a comprehensive climatology of the Nevada Test Site.

SUPPORTED BY U.S. Atomic Energy Commission

1.0022, METEOROLOGICAL STATISTICAL STUDIES

G.W. BRIER, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302 (001140)

Technical Objective: Continue development and application of advanced techniques to geophysical problem analysis.

Approach: Exploitation of the new predictive statistical technique developed by Mr. Brier with applications to a variety of geophysical problems including the prediction of mesoscale winds over time periods of 1-24 hours, the occurrence of solar activity, and the analysis of the error fields resulting from numerical model predictions. Participate in the statistical design of a study testing the influence of urban effluents of air pollution and heat on the distribution of precipitation around a major urban area. As a result of these tests, improvements and advancements were made in the statistical model utilized in making predictions. Provide statistical assistance and analysis to Project Stormfury, to weather modification experiments such as the tropical cloud seeding work of Dr. Simpson.

Progress: Analyses of the solar flare predictability were conducted and improvement in sunspot predictions demonstrated. This has considerable potential for improvement in telecommunications interference forecasting. A new statistical prediction technique for single or multiple time series was developed. The procedure will accept any number of prediction parameters and divide them into influence bands from which prediction equations are derived to calculate the future state of the atmosphere. The model is essentially self correcting and allows for updating the coefficients of the prediction equations as new data arrives. A study, by means of a carefully designed statistical methodology, shows an apparent correlation between jet aircraft flights and the increase in the amount of cirrus clouds.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

1.0023, METEOROLOGY FOR URBAN AID POLLUTION

R. GRASS, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302 (000286)

Support ARL Program Objectives, which are: to relate meteorological elements to the generation, transport and modification and removal of air pollution.

Conduct airborne (helicopter) measurements of ozone, total oxidants and sulfur compounds in conjunction with ARL field efforts to determine a pollution climatology in the Los Angles area.

Data is being evaluated and a report is programmed for the end of FY-70.

SUPPORTED BY U.S. Dept. of Commerce - E.S.S.A.

1.0024, THERMAL MODIFICATION

P.M. KUHN, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302 (001127)

Approach: This program area will continue to materially contribute to the laboratory field efforts: (1) Great Lakes - study the heat island effect of large metropolitan areas such as Buffalo; (2) Mitigation of Severe Storms (Hail) - hailstreak analysis with airborn IR remote probing; and (3) Inadvertent Modification - study of the atmospheric thermal radiation budget.

Progress: In-situ infrared and solar radiometric observations of supersonic and convential jet contrail sheets coupled with radiative transfer calculations have revealed no significant decrease in the mean surface temperature.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

1.0025, METEOROLOGY FOR RADIOACTIVITY

R.J. LIST, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302 (011630)

Collection, quality control, and summarization and analysis of data on radioactivity in the atmosphere and the earth's surface for estimating atmospheric concentrations and fallout levels. These data are used to predict future fallout and to investigate atmospheric processes.

Continued improvement of data collection procedures through development of new sampling devices and exercise of immediate quality control both for the Northern Hemisphere and Southern Hemisphere (Australia) activities. A three-dimensional global diffusion model is being developed for computer simulation in which known injections of radioactivity will be used for verification. This will be a cooperative program with the Geophysical Fluids Dynamics Laboratory. A medium range empirical type K theory box model has been developed and is being tested on the computer facility at the National Meteorological Center activity. Additional tracers (CO_2, H_2O, and naturally-produced radionucludes) will be incorporated both in the data analysis procedures and in the diffusion modelling. Considerable emphasis on three-dimensional trajectories and their verification through the use of known releases of radioactivity will be pursued using the National Meteorological Center's existing model and improvements thereto.

Program to study long term trends of oxygen content of the atmosphere was completed with the results that the oxygen fraction of the atmosphere appears unchanged since 1910. The study of the movement of radioactivity in the stratosphere along sloping isotropic surfaces has successfully indicated the importance of organized circulation systems (Carbon-14 molecular sieve and air ejector whole air sampling) have been successfully tested and operation use initiated. Significant data improvement is expected as a result of these modifications. The study of the movement of radionuclides has now reached the stage that permits numerical simulation and the computer software has been developed for calculation of simplified models as well as preliminary extension to more complex dynamical meteorological models.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

1.0026, METEOROLOGY FOR URBAN AIR POLLUTION RESEARCH

R.A. MCCORMICK, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302 (000350)

Relate meterorological elements to the generation, transport and modification and removal of air pollution.

Conduct research on boundary layer dynamics in urban areas, study the meteorological of secondary air pollution. Conduct field experiments on large power plant effluents. Develop air pollution climatology and pollution potential forecasting. Investigate large scale effects of pollution on weather and climate. Provide consultation, field studies and training programs on meteorology.

Successful completion of a year's study of a large power plant with lidar and aircraft. Support the establishment (by WB) of urban soundings. Completion of urban diffusion analysis. Inaugurate urban boundary layer studies. Complete development of new turbidity instruments on indirect x temperature probe. Conduct numerous field studies in support of NAPCA activities.

1. AIR QUALITY

SUPPORTED BY U.S. Dept. of Commerce - E.S.S.A.

1.0027, METEOROLOGY FOR NUCLEAR REACTORS
I. VANDERHOVEN, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302

Study the transport and diffusion of radionuclides by the atmosphere with emphasis on: dispersion over distances of tens of miles and over time periods of many hours: factors affecting plume deposition and subsequent; depletion; the effect of diffusion in built-up urban areas, and the delineation of diffusion incides and engineering methods to estimate diffusion.

Conduct a full-scale study of the aerodynamic effect of various buildings shapes and sizes on downwind diffusion. Continue controlled experiment to separate and analyze the effects of various types of surface on deposition and depletion. Continue studies to determine what effect 'real' conditions in the near-surface boundary layer and planetary boundary layer have upon transport and diffusion. Obtain quantitative information on the mesoscale flows and its contribution to transport and diffusion of special effluents.

Completed a joint AEC-HEW field study of the characteristics of the urban planetary boundary layer at Columbus, Ohio. Begun computer analysis of derived data to determine comparative vertical motions, variations in Reynolds stresses and trajectories over urban versus rural areas. Investigated the feasibility of realistically depicting mesoscale flow patterns through objective analysis of wind data from a network of wind stations. Published several papers and reports on studies and test results conducted over the past years.

SUPPORTED BY U.S. Atomic Energy Commission

1.0028, ESSA ANTARCTIC METEOROLOGY RESEARCH PROGRAMS
H.K. WEICKMANN, U.S. Dept. of Commerce, Natl. Oceanic & Atmos. Admin., *Boulder, Colorado* 80302

Surface and upper air meteorology research will continue at South Pole Station with the following programs: (1) a qualitative evaluation will be made of the heat and mass budget of the high altitude southern hemisphere region and its relation to the global budgets. (2) the descriptive picture of the atmospheric structure and circulation at high south latitudes over Antarctica and the surrounding oceans will be improved, (3) observed atmospheric motions will be related to known physical laws, (4) further knowledge of the Spring Atmospheric Warming, dynamics of the boundary layer inversion, and mechanics of atmospheric snow transport will be sought, and (5) information about weather modifications (either intentional or inadvertent, by way of gaseous or particulate atmospheric contamination) will be collected. Studies of incoming and outgoing radiation in various ranges from UV to long IR will be continued and related to the radiation balance. All of the above investigations will be made with data collected at Pole Station in CY 1971. The parameters to be measured include temperature, wind velocity, incoming and outgoing radiation, atmospheric composition (CO_2 and O_3) and the size, distribution and concentration of particulates. The data will also be used to evaluate the sounding techniques in use on Nimbus III.

1.0029, GEOCHEMICAL EXPLORATION STUDIES OF VOLATILE ELEMENTS
J.H. MCCARTHY, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

States to which project pertains: Arizona, California, Colorado, Nevada, and Utah.

Measure the distribution and abundance of volatile elements in the atmosphere; study their relationship to ore deposits and application to geochemical exploration. Particularly to measure the concentration of those elements associated with ore deposits that are given off in gaseous form. Mercury anomalies have been found in air over most ore deposits, and SO_2 and halogen gases are to be studied. Evaluate the factors that influence the distribution, abundance, and movement of volatile elements in the atmosphere.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

1.0030, GASEOUS PLUME DIFFUSION ABOUT ISOLATED STRUCTURES OF SIMPLE GEOMETRY
R.N. MERONEY, Colorado State University, School of Engineering, *Fort Collins, Colorado* 80521 (AT(11-1)-2053)

Interest in the mechanisms of gaseous plume dispersal has increased rapidly over the past forty years. Most efforts have been directed toward understanding diffusion in idealized situations. During the last ten years many authors have stressed the importance of understanding the dispersal processes of gas plume in situations of practical importance. In spite of the high quality and extent of these initial tests, the lack of a complete understanding of pollutant behavior in the vicinity of building structures is evident. Many important situations have not been correctly described and the majority of measurements made are not easily correlatable or comparable.

This proposal suggests a systematic experimental study of the air flow and diffusion in the vicinity of simple geometrical shapes. The approach attempts to isolate the peculiarities of such configurations in an effort to make appropriate field predictions possible.

The ultimate objective of this study on gaseous effluent behavior is to help develop a technology which will result in faster, safer and more economical dispersal of gaseous reactor wastes.

Results: During the last half year a set of wind-tunnel measurements have been made for gaseous plumes emitted at the surface of a simple cubical geometry building into neutral and stratified boundary layers. These experiments were designed in coordination with the National Reactor Testing Station which plans to perform a series of equivalent prototype measurements. Gaseous plume behavior was examined by flow visualization techniques utilizing a visible smoke, and by gas tracer techniques using a mixture of Kr-85 and air as a tracer

SUPPORTED BY U.S. Atomic Energy Commission

1.0031, THE BEHAVIOR OF NEGATIVELY BUOYANT GAS PLUMES
R.N. MERONEY, Colorado State University, School of Engineering, *Fort Collins, Colorado* 80521

Recent practice in the air pollution control of fossil-fuel power and heating plants suggests the use of pollution abatement equipment to meet Federal and State pollution standards. Frequently wet flue gas- washing process equipment are used to reduce particulate and SO sub 2 load levels. Unfortunately the flue gases are always cooled and almost certainly become saturated. Subsequently the release of these saturated gases often is followed by vapor particulate evaporation; cloud cooling; and descent of the gaseous plume to the ground. Plume descent by evaporative cooling of entrained water vapor may increase significantly odor, toxicity, and in some cases explosion potential.

Dense plume behavior will be studied in the Micro-Meterological Wind Tunnel at Colorado State University. Measurements of concentration utilizing tracer gases in neutral, stable, and unstable atmospheres will be examined. Modifications to existing plume rise formula will be prepared to allow field computations of wet plume behavior.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0032, THE ROLE OF THE GENERAL CIRCULATION OF THE ATMOSPHERE IN RADIOACTIVE DEBRIS TRANSPORT
E.R. REITER, Colorado State University, School of Engineering, *Fort Collins, Colorado* 80521 (AT(11-1)-1340)

Writing of Vol. IV of a 'critical and creative review' on Atmospheric Transport Processes will commence. This volume will deal with the nature and origin of natural and artificial radioactive trace constituents of the atmosphere, their identification, and their applicability in portraying tropospheric and upper-atmospheric circulation regimes. A composite empirical 'model' of the general circulation, derived from tracer evidence, will be compared with numerical models.

Using conventional and satellite data we will study the stratospheric ozone transport in both hemispheres. Transport processes in the jet-stream region in both hemispheres will also be studied and the relative role of planetary and cyclone waves in these transports will be assessed. The differences in the circulation patterns of the northern and southern hemispheres will be examined.

Vol. I of the review (Energy Transfers and Transformations) is available as TID-24868. Vol. II (Chemical Tracers) is in print as TID- 25314. The manuscript of Vol. III (Hydrodynamic Tracers) is being readied for printing. Data banks for the global ozone and jet stream studies have been established.

SUPPORTED BY U.S. Atomic Energy Commission

1.0033, STUDY OF RELATIONSHIP OF ENGINE DETERIORATION TO EXHAUST EMISSIONS
L. SMITH, Automotive Research Associates, *Washington, District of Columbia*

This contract is designed to determine, on an accelerated basis, the interrelationship of engine wear-incipient component failure and exhaust emission increases that cannot be recovered by normal maintenance as specified in the regulations. The vehicles are to be operated on a 1000 mile-per-day-five day per week schedule with exhaust emission and engine diagnostic measurements at 10,000 mile intervals. Mileage accumulation will continue until major failure, such as valve burning occurs or, until 100,000 miles if no failure occurs. After deficiency correction operation will be extended through 5,000 to 10,000 additional miles to see if emissions return to the original stabilized levels. Engines will receive normal maintenance.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0034, ENERGY, AIR QUALITY, AND THE SYSTEMS APPROACH
G. BLACK, George Washington University, Prog. of Pol. Stud. Sci. Tech., *Washington, District of Columbia* 20037

This study is an analysis of the implications for 1) national energy and fuel resource policy and 2) air pollution policy, the means by which national goals which are dependent on the use of energy, such as economic growth, can be achieved simultaneously with air quality goals. Since the overwhelming portion of air pollutants are the by- product of energy generation, changes in the mix of pollutants which result from alterations in fuels, means of energy conversion, or pollution abatement are of major air quality significance. Special attention is given to sulfur oxides and particulates. The basic energy model is derived from the Department of Commerce interindustry study (input-output table for 1963), from engineering data on: power generation; pollution abatement; vehicular power. The pollution model combines an emitter model, a diffusion model, and a recipient model. The overall model merges the energy and the pollution model so as to permit a comparative analysis of alternative programs, with respect to costs, air quality and technology.

1.0035, ATOMIC REACTION KINETICS
J.T. HERRON, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

Rates of reaction of atomic oxygen with a series of haloethylenes have been measured at room temperature. Particular attention has been paid to the formation of product formaldehydes and halogen substituted formaldehydes which may play a role in air pollution through the burning of halogen containing plastics.

A critical review of rate constants for the reactions of atomic oxygen with methane and ethane has been completed.

A study of the reactions of O2 1 delta g with unsaturated organic compounds has been initiated. Rate constants have been obtained for reactions with simple olefins and more complex ring compounds. From this study it is possible to demonstrate that reactions with the simple olefins are not of major importance in air pollution, contrary to recent speculation. This work is being extended to more complex reactants which may be of importance in other aspects of environmental health.

SUPPORTED BY U.S. Dept. of Commerce - N.B.S.

1.0036, MISCELLANEOUS ENVIRONMENTAL ENGINEERING TESTS (OA)
T.W. WATSON, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

Technical Objectives: To provide engineering services including data obtained as a result of laboratory and/or field investigations on problems dealing with the performance of systems or sub-systems used to control the indoor environment of buildings.

Approach: At the request of government agencies services such as investigations concerning air cleaners, humidifiers, air conditioning equipment, heat transfer measurements, etc., are conducted on a reimbursable basis.

1.0038, CHEMICAL COMPOSITION OF POLLUTED AIR
H.W. WOOLLEY, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

The objective of proposed work under this project is to estimate the magnitude of effects on equilibrium constants and equilibrium compositions in air due to interactions between molecules, with particular regard for substances of interst in atmospheric pollution.

The major portion of the work under this project will involve calculations of the effects on the equilibrium composition of air of added chemical reactions appropriate to various industrial and technological processes as deemed of interest in consultation with Project MAQ management. These processes will include chemical reactions which take place in the automobile power plant.

A second part of the work will include an incidental exploration of comparative rates of change of composition for different constituents in such cases as involve reaction rates for which the dependence on temperature and 'third body' identity are given by empirical equations.

Output Expected: Computer Programs.

SUPPORTED BY U.S. Dept. of Commerce - N.B.S.

1.0039, INFRARED STUDIES IN ICELAND
J.D. FRIEDMAN, U.S. Dept. of the Interior, Geological Survey, *Washington, District of Columbia* 20242

The cooperative U.S.G.C.-National Energy Authority of Iceland (and University of Iceland Science Institute) project, Infrared Studies in Iceland, has been undertaken with the objective of recording on film and videotape the major and changing surface thermal manifestations of the neovolcanic zone of Iceland. The area was selected because of its unique position astride the rift zone of the North Atlantic ridge system.

The project is being carried out by aerial infrared-scanner investigations and concurrent field investigations by Icelandic and U.S.G.S. geologists and geophysicists. The detailed objectives include the determination of the practical threshold of detectability of convective heat transfer at the earth's surface by the airborne IR technique, and the study of the relationship between infrared anomalies and tectonics, seismic events (microearthquakes) and other geophysical anomalies (e.g., resistivity lows). Energy-yiel

estimates of volcanic events and convective heat-flow estimates will be made where possible. Changing anomaly patterns have been of particular interest. The next stages of this project will be continued studies and completion of reports on Hekla and other Iceland volcanoes.

1.0041, CONTINENTAL AEROSOLS IN THE MARINE ATMOSPHERE
J.M. PROSPERO, Univ. of Miami, School of Marine Science, *Miami, Florida* 33149

This grant is for continued research on the concentration and composition of marine aerosols. Special emphasis is placed on the investigation of African dust which transits the Atlantic Ocean carried by the Northeast Atlantic Trades and enters the Caribbean area in high concentrations. A sampling station has operated on Barbados West Indies for the past four years and additional stations will be established in the Cape Verde Islands, on Bermuda and at Miami. Radon 222 will be used as an indicator for continental air parcels and as a tracer to study the interaction of African air parcels with tropical disturbances.

The composition of the aerosols will be analyzed to identify those components which are indicators for specific source regions which will allow distinctions between man made and natural aerosols.

SUPPORTED BY U.S. National Science Foundation

1.0042, PRODUCTION AND DISPERSAL OF PATHOGENIC BACTERIAL AND VIRAL AEROSOLS BY AERATION OF CONTAMINATED WATERS
R. KING, Georgia Inst. of Technology, School of Civil Engineering, *Atlanta, Georgia* 30332

The mechanism of bacterial aerosol production from polluted waters has been demonstrated for selected bacteria. These investigations, however, have not been expanded to include pathogenic bacteria and viruses.

It is proposed to investigate aerosol production from polluted waters as a possible pathway for the spread of tuberculosis and viral diseases.

Effects of tuberculosis have been demonstrated at extremely low concentrations of tuberculosis bacteria in the air. The spread of tuberculosis in the vicinity of certain sewage treatment plants by aerosol formation is, therefore, a possibility. Studies utilizing organisms which demonstrate similar characteristics to Mycobacterium tuberculosis will be conducted. Such an organism may be Mycobacterium smegmatis.

The survival rate of viruses has been shown to be quite high in air. An investigation to demonstrate aerosol formation by aeration of polluted waters as a means of dispersing viruses to the atmosphere will be undertaken using as subjects those viruses which attack bacteria (bacteriophages) to simulate those which are of importance to man.

Experimental equipment will include a controlled atmosphere (wind tunnel) equipped with devices for the aeration of bacterial and viral solutions under varying conditions (simulated sewage treatment processes). Down wind aerosol samples will be collected by means of slit samplers, settling plates, and others, analyzed by means of applicable microbiological techniques, and subjected to statistical analysis.

SUPPORTED BY Georgia Institute of Technology

1.0043, DEVELOPMENT OF IMPROVED TECHNIQUES FOR USING PRESCRIBED FIRE IN SOUTHERN FORESTS
R.W. COOPER, U.S. Dept. of Agriculture, S.E. Forest Experiment Station, *Macon, Georgia* 31202 (SE2101)

OBJECTIVE: Develop improved methods of using fire to reduce fuel areas and to accomplish silvicultural objectives; determine stand, fuel, and weather conditions under which appropriate firing techniques will produce a fire of the required intensity and behavior; to be alert to alternative methods of fuel reduction.

APPROACH: Developing improved instrumentation for documenting both the prescribed fire and its environment. Time-temperature relationships, heat yield, and flame characteristics are of primary interest. Continuing studies on firing techniques. Studying the use of prescribed fire for fuel or hazard reduction. Evaluating other promising means of hazard reduction or prevention of fire from hazard areas.

PROGRESS: Prescribed burning is normally a daytime operation, but research has shown that productive burns can be accomplished at night as well. Forest fires, both wild and controlled, produce changes in air quality that are not fully understood. Products of forest fuel combustion are CO(2), H(2)O, CO, and minor amounts of hydrocarbons. Sulfur products are apparently not present in significant amounts. Particulate concentrations are highest immediately downwind from the burn and taper off as samples are taken further from the source. Particulates produced by burning forest fuels are commonly in the 0.2 to 0.5 micron range--smaller than other common sources of pollution. Predicting crown weights of loblolly pine from standard crown data can be accurately done using d.b.h. for both Piedmont and Coastal Plain trees. These data can be used in planning fuel reduction measures for thinnings and harvest cuttings. Controlling fire intensity in hilly terrain may be partially accomplished by using the 'Chevron' burning technique. Predicting tree mortality in young stands is closely related to the amount of crown consumption and bole damage resulting from free- burning fires.

SUPPORTED BY U.S. Dept. of Agriculture

1.0044, CONTUNUOUS MEASUREMENTS OF AIRBORNE AND PRECIPITATION RADIOACTIVITY AND METEOROLOGICAL APPLICATION
R. REITER, Physicalisch Bioklim. Forsc., *Munich, Germany* (AT(30-1)4061)

The object of this project is to identify the mechanism of the air mass exchange between stratosphere and troposphere.

The radionuclides P32 and Be7 are predominantly produced in the stratosphere by cosmic rays. Hence, the variations of their concentrations with time measured at an undisturbed location indicates the variations of the influx of stratospheric air to the measuring site. For interesting periods it is possible to describe the mechanism of air mass exchange stratosphere and troposphere by a detailed analysis of he meteorological conditions prevailing in the lower stratosphere, tropopause and troposphere. Jetstream formation, topography of the tropopause, and temperature distribution in the troposphere are also taken into account.

In order to gain the basic data for this work membran. filters are exposed daily at Zugspitze peak (3000 m a.s.l.) with 2000 cu m air per 24 hours. The radionuclides P32, Be7 and some fallout elements are separated chemically and their concentrations measured by beta- and gamma-ray spectrometry.

From April 1, to December 1, 1970, 227 filters have been exposed and analyzed. Comparisons between the variations of the radionuclide concentrations and meteorological data (radiosonde ascents of Atlantic and Europe) have been made by computer techniques.

Results: It was found that there is a strong correlation between the influx of radioactive aerosol from stratosphere to the measuring site and typical variations of tropopause structure and jetstream formation. It has been possible to fix exactly the location where an injection of stratospheric air had taken place. By the continuity of the series of recordings and measurements and by a modification of the computing technique it will be possible to deduce laws which control the mass exchange between stratosphere and troposphere.

SUPPORTED BY U.S. Atomic Energy Commission

1.0045, AIR-SPORA IN HAWAII
I.W. BUDDENHAGEN, Univ. of Hawaii, School of Agriculture, *Honolulu, Hawaii* 96822

The qualitative and quantitative nature of the air spora in Hawaii is to be investigated by sampling the atmosphere with spore-trapping devices. Special attention will be given to spores of plant pathogenic fungi and spores and pollens of suspected and known allergens. Total spore loads in agricultural and urban areas will be compared. Attempts will be made to detect biologically significant particles in the atmosphere at the Mauna Loa Observatory on the Island of Hawaii (elevation kk,150 feet), and to determine their likely points of origin. At Atlas of air-borne spores in Hawaii will be compiled. The processes of spore formation, release and dispersal are to be studied and the effects of meteorological and other factors on these processes will be studied.

1.0046, CHICAGO AIR POLLUTION SYSTEMS MODEL
J.E. CARSON, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

A numerical model to simulate and forecast SOsub2 pollution concentrations in Chicago from source emission and meteorological data and forecasts is being developed under a joint contract with the Department of Environmental Control, City of Chicago, and the National Air Pollution Control Administration. A secondary objective of the study is to develop and test effective and economic pollution abatement techniques, using the SOsub2 diffusion model as a component. The Meteorology Group has participated in the program by supplying meteorological data and advice, identifying and analyzing meteorological conditions causing high pollution levels, operating experimental programs to measure diffusion parameters and dispersion rates, and developing a receptor-oriented urban pollution model.

This summer, an extensive series of diffusion experiments will be made in chicago, using SFsub6 as the tracer. The analytical studies will be continued.

Results: The numerical prediction model has been developed and is being verified. Three pollution abatement exercises, the fuel-switch tests, have been conducted in the City of Chicago. Chemical analysis procedures for SFsub6 have been developed; a sensitivity of 0.5 parts per 10super12 parts of air has been achieved. The Tabulation Prediction Scheme, a receptor-oriented urban model, has been completed. Numerous helicopter surveys have been made. Several published reports and papers presented at scientific meetings have been generated by the Meteorology Group.

SUPPORTED BY U.S. Atomic Energy Commission

1.0047, PLUME RISE STUDIES
H. MOSES, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

A state-of-the-art study is being made to determine techniques for determining plume rise. This study consists of a review of the basic thinking in this area as well as a summary of measuring techniques. An analysis and critique of the theory underlying current plume rise summaries are being made. Plume rise data based on single stacks from all over the world have been assembled. An objective of this study is to develop recommendations concerning the best techniques for calculating plume rise.

Results: Most of the background material discussing the historical development, measuring techniques, and basic theory has been written up. Preliminary computer runs testing currently used formulas with data sets have been completed.

1.0049, WORKSHOP ON GLOBAL ECOLOGICAL PROBLEMS
R.F. INGER, Field Museum of Nat. History, *Chicago, Illinois* 60605

Twenty or more leading ecologists will be convened by the Inter- American Institute of Ecology to evaluate environmental issues, the results to be offered as a Basic Paper for the UN Conference on the Human Environment scheduled for Stockholm in 1972. Four to six critical ecological problems will be studied, selected on the basis of their global and international significance and on the basis that the science of ecology can usefully be applied toward their clarification or solution. The workshop will be patterned after the Williamstown, Mass. Study of Critical Environmental Problems (SCEP) sponsored by the Massachusetts Institute of Technology in 1970 and published in the report Man's Impact on the Global Environment. It will build on the ecological section of that report.

SUPPORTED BY U.S. National Science Foundation

1.0050, MINERAL MATTER IN COAL
H.J. GLUSKOTER, Univ. of Illinois, State Geological Survey, *Urbana, Illinois* 61801

The investigation is concerned with the nature, distribution and origin of the inorganic constituents of coal. In order to obtain a relatively unaltered sample of mineral matter from coal to use as a starting material for our investigations, an electronic low-temperature ashing technique is routinely used. After ashing the coal at temperatures below 150 degrees C, the mineral matter residues are investigated by x-ray fluoresence spectroscopy, atomic absorption spectroscopy, optical emission spectroscopy, neutron activation analyses, and general wet chemical methods for elemental analyses; and by sieve and Coulter Counter analyses for size determination.

In recent years this research has resulted in publications concerning chlorine in coal, the mode of occurrence of sodium and chlorine in coal, sulfur in coal, clay minerals in coal, phosphate minerals associated with coals, and mercury in coal.

Studies of the areal distribution of the minerals in coals of the Illinois Basin, the use of boron content as a paleosalinity indicator of coals, and the heavy metal (As, Hg) concentration in sulfide minerals in coals are all currently being actively pursued. The results of these investigations will, hopefully, be published during the next one or two years.

1.0051, NUMERICAL ANALYSIS OF TURBULENT FLUID FLOW MIXING
W.L. HULL, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

An implicit finite difference technique is used to solve the combined conservation equations of a turbulent, constant pressure, non- homogeneous, axisymmetric fluid flow mixing problem for various flow field parameters.

This problem is applied to mixing conditions between the venturi and the throttle plate of a carburetor. This model is then applied to optimize the conditions governing the mixing of fuel and air in an effort to get a more homogeneous mixture, enabling improved mixture distribution wih consequent improvements in fuel economy and reduced exhaust pollutants.

1. AIR QUALITY

SUPPORTED BY Ethyl Corporation - Richmond, Va.

1.0052, INTERDISCIPLINARY STUDY OF ENVIRONMENTAL POLLUTION BY LEAD
R.L. METCALF, Univ. of Illinois, Graduate School, *Urbana, Illinois* 61801

The proposed research involves the planning and development of a comprehensive study on environmental pollution by lead with special emphasis on lead from gasoline but including the movement of all forms of lead through the environment. The various states, processes, transformations and transportation agents by which lead migrates from its original points of deposition to its final destination will be examined. Concurrent with the above model development will be the development of a systematic procedure for the location, collection and evaluation of data relevant to the diverse aspects and processes involved in environmental pollution. An integral part of the planning will involve the establishment of an analytical facility to develop and test methodology.

Specialists in agriculture, engineering, biochemistry, physiology and medicine, economics and law will assist in the development of a comprehensive research program. Collaboration with investigators from other institutions has been assumed.

SUPPORTED BY U.S. National Science Foundation

1.0053, RESEARCH INITIATION - DISPERSION OF POLLUTANTS FROM TALL CHIMNEYS.
D.L. BRENCHLEY, Purdue University, School of Engineering, *Lafayette, Indiana* 47907

Tall chimneys are used as an effective method of dispersing effluents. Under certain meterorological conditions, however, a phenomenon called 'fumigation' can cause relatively high concentrations of pollutants at certain ground locations. This research will employ a gaseous tracer technique in order to study this process. Field measurements will be correlated with the various models which have been proposed for calculating the ground level concentrations.

SUPPORTED BY U.S. National Science Foundation

1.0054, PRODUCTION PRACTICES FOR FRUITS
R.A. HAYDEN, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01347)

OBJECTIVE: Develop pollution-free methods of combating cold injury to fruit plants. Study the effects of rootstock and training on hardiness of peach. Evaluate fruit varieties in Indiana's climate.

APPROACH: Study methods of protecting fruit plantings from frost and low winter temperatures through heating with oil, propane and electricity emphasizing systems free of air pollution. In Purdue Orchards, develop planting and training systems for peach trees on standard and dwarfing rootstocks for adaptation to Midwestern climatic conditions. Continuously evaluate in Purdue and grower orchards, apple, peach and strawberry varieties for adaptation to the midwest.

PROGRESS: Oil, propane and electric heating systems were installed in an apple orchard. Oil system operated satisfactorily providing 3 to 5 degrees of protection against spring frost. Propane system also operated satisfactorily, except that the problem of fuel vaporization would be severe in a larger installation. Protection was 3 to 5 degrees. Electric system gave only minimal protection of one to one and 1/2 degrees, and appears at this point to be impractical for commercial orchards. Evaluation of apple and strawberries varieties continued. Significant differences occured in the precocity, yield, color, and desirability of various strains of Delicious apples tested. Peach plantings were established to study pruning, population, and yield potential of close plantings of peach. Hardy varieties of peach were worked on 2 hardy peach rootstocks to study effect of all combinations on tree performance under Mid-Western environmental conditions.

SUPPORTED BY U.S. Dept. of Agriculture

1.0055, SWINE HOUSING ENVIRONMENT
T.E. HAZEN, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01596)

OBJECTIVE: Develop and verify design criteria for control of air quality for swine production.

APPROACH: Test building constructed to house swine and control resulting atmosphere for identification. Chromatographic technqiues to be used to separate and identify atmospheric gases. Variations in management, temperature, humidity and ventilation will be studied as they effect gaseous composition. Several compositions of steel will be exposed to identify effect of atmosphere on corrosive properties. As progress permits the effects of the various gases on animal performance will be studied.

PROGRESS: Thirty gaseous compounds have been identified to date in a hog house atmosphere. Of these two groups, amines and mercaptans, have been subjectively associated with undesirable odor. Procedures for quantitatively measuring and numerically indexing the atmospheric quality have been only partially successful. Approximately 16 steel- based materials are being exposed to the atmosphere and periodically evaluated for resistance to deterioration. Of the gases identified, those of corrosive interest are being quantitatively measured. Of related interests are observations on the physical properties of the atmosphere and of animal management practices as they affect both the subjective and measured quality of the atmosphere.

1.0056, VEHICLE AND HIGHWAY SAFETY ON WINTER TIRES, WINDSCREENS, BRAKING SYSTEMS AND AIR POLLUTION
G. POCCI, Italian Min. Transp. Civ. Avn., *Rome, Italy* (2R52061118)

Tests are being conducted to determine the relative safety and to establish standard specifications for metal studded tires, braking systems, windshields, and air pollution. The effect of metal studs embedded in the tire on the reduction of skidding on icy roads is being tested in the laboratory. Various types of glass used in windshields were tested to determine the relative safety features of each. The accumulation of carbon monoxide in the interior of passenger cars during idling was also investigated.

Document provided to SIE by the Highway Research Information Service.

SUPPORTED BY Italian Government

1.0057, SELENIUM AND ITS SIGNIFICANCE AS AN AIR POLLUTANT
P.W. WEST, Louisiana State University, Graduate School, *Baton Rouge, Louisiana* 70803

Perfected sampling and analysis techniques would now be applied to the study of sources of selenium and its distribution. Previous work on this project has proved that selenium concentrations reported by other investigators are incorrect because of improper sampling techniques that were used. We have found SeO sub 2 as high as 240 mu g per cubic meter which is approximately two orders of magnitude higher than the highest values reported elsewhere. The common use of high-volume samplers or other filtration methods leads to the proposed studies will be based on samples that are collected by scrubbing to obtain stable aqueous systems that will be analyzed by the specific catalytical method developed during the first phase of the project. Incinerator emissions would be evaluated as would a variety of other sources of selenium such as diesel exhausts, stump burning, etc.

1.0060, KINETICS OF NO AND CO FORMATION IN COMBUSTION GASES
J.C. KECK, Mass. Inst. of Technology, School of Engineering, *Cambridge, Massachusetts* 02139

The mechanism of NO and CO formation in combustion gases will be investigated theoretically and experimentally. The theoretical program involves the developmett of a rate-controlled partial-equilibrium method for treating complex reacting gas mixtures. The method will be used to develop improved models of the freezing of NO and CO in Rankine cycle burners and during the expansion and blown of an internal combustion engine. The experimental program involves the development of improved diagnostic techniques for the detection of NO by absorption and scattering of light and the application of there techniques in shock tube studies of NO formation in hydrocarbon rich combustion products at high pressures. The formation of NO and CO in atmospheric pressure flames will also be studied in a burner designed to simulate the features of a Rankine cycle combustion chamber.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0061, 1970 SUMMER STUDY ON CRITICAL ENVIRONMENTAL PROBLEMS
C.L. WILSON, Mass. Inst. of Technology, School of Management, *Cambridge, Massachusetts* 02139

A summerstudy of four weeks is proposed for the month of July 1970 which will bring together about forty scientific and professional experts from many disciplines, and from the academic, government, and private sectors.

During the Study, the global climatic and ecological effects of pollutants in the atmosphere-ocean system will be analyzed, and procedures for understanding, monitoring, and abating these effects will be extensively explored. The Study will outline the types of focused research, monitoring and modelling programs which will be required tc obtain definitive knowledge about these effects. The pollutants to be considesed will include the following: CO2, particulate matter, combustion products, water vapor, heat, inorganic and synthetic compounds, and phosphorous-nitrogen-potassium.

Approximately 60 scientists will participate in the study with scientists from federal laboratories and various federal agencies included. About 40 scientists from non-federal institutions will participate. No participants from Eastern European nations are expected to attend.

1.0065, COMBUSTION PRODUCTS FROM THE INCINERATION OF PLASTICS
E.A. BOETTNER, Univ. of Michigan, School of Public Health, *Ann Arbor, Michigan* 48104

Combustion products of three plastics (polyimide, polycarbonate, and polysulfone) are currently being studied under various conditions of temperature and air supply and work on a fourth plastic (polyphenylene oxide) has been completed. Purposes of this research include determination of products which could be air pollutants or corrode equipment on incineration, analysis of products at various stages of the combustion process to aid those currently designing incineration systems capable of recovering by-products for their fuel or crude chemical value, and evaluation of the toxicity of combustion products. Work on polyethylene, polystyrene, and polyurethane are scheduled to begin shortly.

Polyphenylene oxide and polycarbonate present minimal pollution and corrosion problems as they break down almost completely to CO sub 2 and water under incineration conditions. Under deficient oxygen conditions, they depolymerize to form phenol and substituted phenols, small amounts of hydrocarbons, CO, CO sub 2 and water. The phenols are in condensed form and could be recovered. Polyimide forms CO sub 2, CO, water, ammonia, cyanides and oxides of nitrogen under incomplete combustion conditions. The nitrogen compounds can present a pollution problem. Polysulfone gives off SO sub 2 as well as CO sub 2, CO, water and hydrocarbons. It thus presents pollution and corrosion problems.

1.0066, AIR STERILIZATION
D.R. HELDMAN, Michigan State University, Agricultural Experiment Sta., *East Lansing, Michigan* 48823 (MICL00703)

OBJECTIVE: Isolate and investigate methods of controlling airborne microorganisms in food processing plants; determine mechanisms causing transport of airborne microorganisms from source to point of contamination; investigate methods of providing localized control of airborne contaminants.

APPROACH: Study food processing plant operations - processing and packaging and dispersion of bacterial aerosols in an enclosed space.

PROGRESS: Research during the indicated project period has dealt with improvement of air quality in enclosed spaces by (a) evaluation of potential sources of air-borne contamination, (b) factors influencing air-borne microorganism populations and (c) the description of surface deposition by small particles. The role of a flat surface as a source of air-borne contamination was determined by investigating mechanisms influencing removal of small particles (5-40 mu) from the d surface. The new two-part mechanism of particle re-entrainment was proposed and verified. Free-stream air turbulence was found to have a significant in-

fluence on the degree of particle re-entrainment. The results illustrate that flat surfaces of sufficient size can be a source of airborne particles even at low air velocities which exist in enclosed spaces. The influence of temperature and relative humidity on viability of air-borne Salmonella newbrunswick was investigated. Results indicated that death rate was decreased when skim milk was used in place of water as a suspension medium. The introduction of a bi-polar oriented electrical field into an enclosed space reduced the air-borne microorganism population by 37 to 62% depending on species present. The field tended to increase deposition on surfaces but increased death rates seemed to contribute, also. A mathematical expression to describe bacterial aerosol diffusion and deposition was developed. The influence of source height above deposition surface and aerosol generation rate on location of deposition was illustrated.

1.0067, URBAN CLIMATOLOGY

D.G. BAKER, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-25-066)

OBJECTIVE: Provide a detail d study of the climate of metropolitan St. Paul-Minneapolis and surrounding rural area including local (on micro-) climates within. Investigation will be made into such questions as the actuality of a temperature differential and its magnitude between urban and rural sites, the influence of the city upon local precipitation, and the presence of a heat island its demarcation.

APPROACH: The investigation will be based upon the data available from the dense network of 24 cooperative observing stations and one Class A Weather Burea station, and also upon meterological data taken from moving vehicles specifically for this study.

PROGRESS: A special map of the Twin Cities metropolitan area was drafted that can be printed as either a station locator-plotting map or an analysis map. The area mapped is about 6300 square miles and the detail even includes township numbers. The Weather Bureau has printed several hundred copies of the weather analysis map for our use. The maps are required for the detailed study of the temperature and precipitation of the metropolitan area. Precipitation data from 4 different agencies were assembled and the acceptable data analyzed in detail for a 5 year period. Ten years data have been analyzed in less detail. The analysis is centered upon the areal distribution of precipitation within the metropolitan area. As a follow-up to a study on temperature inversions in an urban environment (see publication list), we are analyzing low-level temperature inversion data from a sod covered plot in a nearby rural environment.

1.0068, PARTICLE DYNAMICS

M.R. SMITH, Mississippi St. University, School of Engineering, *State College, Mississippi* 39762

This study is designed to determine the effect of meteorological conditions and engine characteristics on the diffusion of exhaust clouds produced by rocket engines. This program is motivated by personnel safety considerations and the desired result of the program will be a diffusion model that is capable of predicting gas concentrations profiles such that toxic exclusion distances may be reliably established.

Due to the complexity of the associated aero-thermodynamics phenomena, the development of a specific diffusion model appeared unfeasible; therefore, a numerical simulation of the diffusion process has been attempted using a high-speed digital computer. A two- dimensional numerical simulation model has been developed and programmed on a high-speed digital computer. The initial results indicate that the method has considerable potential. Presently the model is being programmed on a large computer so that the field size can be enlarged and grid size decreased. This should result in greater accuracy of the numerical simulation.

The experimental phase of this project is being conducted at the NASA-Miss. Test Facility, Bay St. Louis, Mississippi. During the past eight months, experimental data have been acquired on three (3) S-IC static firings. Photographic records have been made of the growth and dissipation of the associated rocket exhaust cloud and airborne acquisition of meterological data and cloud data has been employed to define the characteristics of the exhaust cloud. The airborne data acquisition system has been fabricated at the NASA Mississippi Test Facility utilizing an excess telemetry system. The system has been modified to permit simultaneous on-board recording and telemetry to the MTF Data Handling Center where the data are processed in real time.

1.0069, PARTICULATE POLLUTANT SYSTEM STUDY - MODIFICATION AND EXTENSION

VANDEGRIFT, Midwest Research Institute, *Kansas City, Missouri* 64110

Objective: Complete the study.

Description: The modification entails a time and money extension to the contract to permit the estimation of fine particle emissions from significant sources and the projection of these emissions through the year 2000. In addition an extension was requested by Midwest Research Institute to complete the present study. It is the purpose of this present study to estimate total particulate emissions and project these through the year 2000 and to tabulate the important particulate and carrier gas stream characteristics for each significant emission source.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0070, AEROBIOLOGICAL SURVEY IN THE NORTHERN ROCKY MOUNTAINS AND PLAINS

W.E. BOOTH, Montana State University, Graduate School, *Bozeman, Montana* 59715

This project now is going into its third year and has given measurements of the air borne particle load over natural grasslands in central Montana. Identifacation of pollen grains and most of the larger particles have been made; they have in turn been correlated with the plant community over which the samples were taken. Certain climatological data is associated with air borne materials in an attempt to explain the variation in the amount of the particulate air load.

The next phase of the project will be the examination of the smaller particles that are below the range of the light microscope. This study will make use of the electron microscope and the scanning electron microscope. Weights of the smaller particles per volume of air have been taken, but there is a need to substantiate these findings with another set of data.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0071, CONTROL AND USE OF FIRE PARTICULARLY IN WILDERNESS, PARK, AND OTHER RECREATIONAL AREAS

C.E. HARDY, U.S. Dept. of Agriculture, Intermtn. For. & Rg. Exp. Sta., *Missoula, Montana* 59801 (INT2102)

OBJECTIVE: Incorporate research findings into the most effective means of solving the fire control problems of wilderness, park, and recreational area management. Determine how to use fire in resource management and the fire retardant material characteristics most suitable for fire control.

APPROACH: Develop a problem analysis of wilderness, park, and recreational area management in reference to fire control needs. Determining use of fire for hazard reduction and other land management purposes. Screen fire retardant chemicals for suitability in fire control. Other research will focus on fire danger rating and its interpretation by user agencies.

PROGRESS: Investigations into the effects of ammonium sulfate and diammonium phosphate on pyrolysis and combustion of cellulose using thermal analysis methods show distinct differences. Ammonium sulfate decomposes at lower temperatures, and may be unavailable to alter reactions at the time glowing combustion occurs. Correlation of pyrolysis and combustion data with data being taken during wind tunnel burning tests may assist in understanding the overall effect of retardants on flammability. Replication of slash burning treatments within the western larch--interior Douglas-fir forest type confirmed our ability to predict:

(1) fuel consumption, (2) duff reduction, (3) water- can weight loss, and (4) convection column height from broadcast fires in 1-year-old fuels. Prediction equations derived from this large scale cooperative study are benefiting hazard reduction, tree regeneration, wildlife habitat, watershed, and air pollution control programs. An EDP program which computes and summarizes fire-danger indices is available to use with teletype collection of fire-weather data. A handbook being prepared will serve as a primary reference for installation, maintenance, and operation of fire-weather stations and instruments; it will be applicable nationwide.

SUPPORTED BY U.S. Dept. of Agriculture

1.0072, URBAN AIR POLLUTION AND CLIMATIC CHANGE
P. SQUIRES, Univ. of Nevada, Desert Research Institute, *Reno, Nevada* 89507

The underlying practical objectives of these efforts will be to measure the contribution of urban areas to the pollution of the atmosphere as reflected by the urban addition to the atmosphere of specific aerosols. A further practical objective is the assessment of the influence of specific pollutants on the formation and distribution of precipitation as a factor in climatic change resulting from urban contamination. Initially, direct physical measurements will be made of the meteorologically active particulate component in the contaminated plume of air generated in cities. This will be used to obtain an indication of the contribution of such particles to the atmosphere as a whole by the cities in the U.S. When this contribution is compared with natural production rates, it will give an estimate of the continental- scale significance of urban pollution in relation to the microphysics of clouds and the formation and distribution of precipitation, and thereby an estimate of the contribution of urban air pollution to climatic change.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0073, NATURAL CONCENTRATIONS OF SILVER AND IODINE IN PRECIPITATION
J.A. WARBURTON, Univ. of Nevada, Desert Research Institute, *Reno, Nevada* 89507

Ice core samples 3 ft. long by 3 inches in diameter will be collected at South Pole, Byrd, Siple and McMurdo in austral summer 1971- 72 in order to determine absolute concentrations of silver and iodide at points in Antarctica and to compare the efficiency of methods of removal of particulate matter from the atmosphere. The methods by which particulate matter is removed from the atmosphere include wash out, rain out, diffusional collection by sublimation, electrification, riming, and vapor pressure gradients. The precipitation forms at a coastline or inland station are very different; riming being a coastal phenomena whereas diffusional growth accounts for practically all the precipitation at inland stations. The different growth characteristics may result in different scavenging properties for different particles. Deep cores will be used to establish natural base line, pre large scale weather modification seeding, levels of atmospheric sodium and iodine. Comparison will be made with samples from seeded and unseeded lower latitude areas in order to learn about the N-S transport of seeding materials which could have effect on climatic changes, the ecological and sociological effects which may result, and on military applications and international relationships. The silver and iodine will be extracted by ion exchange methods and their quantities determined by neutron activation analysis. The analysis technique includes activation of a known standard of silver and iodine at the same time as the unknown thus obviating changes which could occur in thermal neutron flux, transfer time, counting geometry or other unknown variables.

1.0074, NITROGEN-OXIDE KINETICS IN AUTO COMBUSTION EXHAUST
R.F. MCALEVY, Stevens Institute of Technol., School of Engineering, *Hoboken, New Jersey* 07030

Nitric oxide (NO) is emitted as a combustion product in modern, automotive internal combustion engines. In centers of high population density there is mounting evidence of a health hazard caused by this air pollutant.

Experiments conducted to date using a mechanical analog for the spark-ignition engine, have yielded data on the steady state concentrations of nitric oxide inside the cylinder at different fuel-air ratios, initial pressures and temperatures following different rates of combustion product expansion.

During the period of the continuation of the grant, work will continue on obtaining time resolved concentration data during combustion at different distances from the center of the piston simulator. Work will also continue on the theoretical model which would predict the spacial and temporal variations of the nitric oxide concentration inside the simulator during compression and expansion. Fuel-air concentration mixtures will be the same as they exist in a high compression engine.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0075, GASOLINE COMPOSITION AND VEHICLE EXHAUST GAS POLYNUCLEAR AROMATIC CONTENT
T.W. STANLEY, Standard Oil Co. of New Jersey, *Linden, New Jersey* 07036

Determine the emission rates of polynuclear aromatic hydrocarbons and phenolics as these rates are influenced by: fuel composition, engine operating variables, and exhaust emission control systems. Determine the effect of the following factors on the emission of selected polynuclear aromatic and phenolic compounds: (1) The effects of lead antiknock (a) instantaneously, as a result of its presence in the fuel being tested, and (b) long-term as lead residues appear in deposits, or disappear by extended use of reduced-and zero- TEL gasolines. (2) The effects of increased fuel aromatics content. (3) The effects of fuel PNA content. (4) The effect of heavy catalytic naphtha as a potential source of high-boiling aromatics that are not PNA, but may act as PNA precursors beyond their expected contribution to overall aromaticity. (5) The effect of current exhaust emission control systems. (6) The effect of any available advanced exhaust emission control systems (7) The effect of NOx reducing systems.

Routine measurements of total hydrocarbons, CO, CO2, and NOx will be made.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0076, CHANGING VEGETATION AND ATMOSPHERIC POLLEN
M.F. BUELL, Rutgers the State University, School of Arts, *New Brunswick, New Jersey* 08903

This work has been directed at describing changes in atmospheric pollen and vegetation which have occurred with the recent suburbanization of northeast New Jersey. It has utilized data from past and present aeroallergen surveys taken daily by gravity slide and rotoslide methods; data derived from pollen deposited in the sediments of man-made lakes; and data from contemporary pollen produced in various land-uses including rural, suburban, and urban land-uses.

Past aeroallergen surveys and reservoir sediments indicate declining weed pollen production with changeover from rural to urban land-uses. Strongest in grass pollen and weakest in ragweed pollen, this phenomenon is also evident in contemporary land-uses, but to a lesser degree than in the past.

To provide local allergists with the details of northeast New Jersey's recent atmospheric pollen history, the relationship between land-use and atmospheric pollen in both the past and the present, and to provide an up-to-date calendar of local pollination the authors are presently writing a manual for the allergists of northeast New Jersey which encompasses these topics as well as illustrating for identification purposes the types of pollen encountered in routine pollen sampling in this region.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0077, ARAP MODEL
C. DONALDSON, Aeronautical Res. Associates, *Princeton, New Jersey* 08540

The method of 'invariant' modeling, as developed by ARAP, will be further developed to the stage where it can be specifically applied to the calculation of the dispersion of an inert pollutant released into the lower layers of the atmosphere, under various conditions of atmospheric stability. Theoretical results will be compared with observational data.

1.0078, INCINERATION--COMBUSTION OF PLASTICS, FILMS, ETC.
T. ROTHMAN, U.S. Air Force, Weapons Laboratory, *Albuquerque, New Mexico* 87117

Technical Objective: The objective of this study is to determine the gaseous products resulting from the incineration of the plastics found in municipal refuse. Results will determine need for Air Pollution Control techniques or devices to reduce pollution potential from the burning of plastics. Techniques and information will be applied to studying the combustion products, and need for their control, generated by the incineration of film.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0079, TRAVELS OF AIRBORNE POLLEN
E.C. OGDEN, New York State Mus. Serv., *Albany, New York*

The basic objective of the proposed research is to gain a better understanding of pollen dispersion, transport and removal in the atmosphere. This objective includes four separate but related aspects: 1. Study of pollen dispersion over intermediate distances (tens of miles) and heights to ten thousand feet using an aircraft-mounted isokinetic sampler. 2. Continued study of the efficiency of forested areas and strips of vegetation, comparable to greenbelts or shelter- belts, for filtering pollens and other particulate matter from the atmosphere. 3. Study of the variation in time and space of natural pollen concentrations at both rural and urban locations, not directly influenced by local sources, to determine peak to mean concentration ratios over various sampling intervals and to assess the representativeness of single station measurements. 4. Continued study near local sources of the diurnal pollen emission patterns of plants producing potentially allergenic pollens and variation in concentration with height, time, source, location, terrain, vegetation and weather.

1.0080, MECHANISM FOR THE WATER-TO-AIR TRANSFER AND CONCENTRATION OF BACTERIA
D.C. BLANCHARD, State University of New York, Graduate School, *Albany, New York* 12203

This proposal is for research to investigate the transfer of bacteria to the surface of water from underneath and thence to the air by bubbles which rise in the water and then break at the surface ejecting droplets into the air.

Experiments by the principal investigator have shown that in this way, bubbles can transport organic matter from the main body of the liquid to the surface layer and then transfer it thence to the air. Such droplets have been found by the principal investigator to contain 10 to 1000 times the concentration of bacteria found in the body of water and this concentration varies with droplet size.

A series of experiments will investigate concentration droplet size effect, the ratio of live to dead bacteria, and the effects of different or multiple bacteria species. Bubbles are easily produced in natural bodies of water and this mechaaism for the concentration and transfer of bacteria or possibly virus to the atmosphere could be of considerable significance.

SUPPORTED BY U.S. National Science Foundation

1.0081, ELECTRIFICATION OF DUST STORMS
A.K. KAMRA, State University of New York, Graduate School, *Albany, New York* 12203

The objective of this research is to clarify the mechanisms of charge generation, to gatner data on the electrical characteristics of dust storms, and to estimate their contribution to the electrical budget of the atmosphere. A program of field and laboratory experiments is proposed.

The laboraory experiments will involve the movement of dust by air and the measurement of the charging that occurs under controlled yet variable conditions.

The field experiments will be conducted at an appropriate region in the Southwest where dust storms occur with reasonable frequency. Potential gradient, point discharge currents and space charge will be among the variables measured together with wind speed, temperature and humidity.

SUPPORTED BY U.S. National Science Foundation

1.0082, A STUDY OF THE FACTORS CONTROLLING THE FORMATION OF LARGE NUMBERS OF CONDENSATION NUCLEI IN CLEAN GLOBAL AIR
V.J. SCHAEFER, State University of New York, School of Arts, *Albany, New York* 12224

The objective of this research is to investigate the apparent strong enhancement of condensation nuclei by turpenes in apparently clean air. Evidence supports that turpene vapor polymerizes clusters of molecules to form condensation nuclei in very high quantities in air which originally had a low nuclei content.

Field studies, including the effects of light on these phenomena, will be carried out in the Adirondacks and at Schenectady airport. Laboratory studies will be performed in the large fog chamber at SUNYA (State University at Albany).

1.0083, NON-EQUILIBRIUM EFFECTS IN AN INTERNAL COMBUSTION ENGINE
W. CHINITZ, Cooper Union, School of Engineering, *New York, New York* 10003

Analyses of samples of the exhaust gas from internal combustion engines indicate substantial departure from equilibrium for species such as nitric oxide and carbon monoxide, leading to larger quantities of these species than would be predicted. In this investigation, we will determine the non-equilibrium composition and thermodynamic properties of the combustion gases at various points in the engine cycle, with the objective of relating the quantities of unburned hydrocarbons and oxides of carbon and nitrogen to the engine operating variables. Analytical, as well as experimental verification of the effects of the engine variables on the production of atmospheric pollutants will be sought. Methods for reducing the level of these pollutants by altering the kinetics of the combustion process will be determined.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0084, CRC AIRCRAFT EXHAUST STUDY GROUP
M.K. MCCLEOD, Coord. Research Council, *New York, New York*

Participate in joint activities with aircraft powerplant manufacturers, aviation fuel producers and other government representatives on cooperative studies designed to evolve acceptable techniques for obtaining all types of emissions data from aircraft.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0085, DOCUMENT ODOROUS CONSTITUENTS IN DIESEL EXHAUST
A.E. ZENGEL, Coord. Research Council, *New York, New York*

Continue with research presently in progress under joint sponsorship of CRC-APRAC Project Group CAPE-7 on the isolation and identification of specific odor-causing materials in diesel exhaust. Document in terms of odor qualities or types and develop similar odor measurement techniques.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0086, FORMATION OF THE STRATOSPHERIC AEROSOL
J.P. FRIEND, New York University, School of Arts, *New York, New York* 10003

The objective of this research is to continue an investigation into the mechanisms of formation of stratospheric sulphate aerosol. A laboratory system has been designed and built and the generation of particles at ground level temperatures and pressures investigated. The research vessel can be evacuated down to 10 to minus the 3rd power torr and can be maintained at a fixed temperature over a wide range. Low concentrations of gases such as sulfur dioxide and ammonia are introduced through permeation membranes. Photochemical reactions can be studied and particles created by such reactions are monitored through a sampling manifold by scattering techniques or by a condensation nuclei counter.

The proposed research will continue to test the ability of various combinations of possible reactions and reactants to produce particulate sulphates and to study in detail the kinetics of the more significant reactions. Model studies will be performed of the effects of eddy diffusion and reaction rates on the distributions of sulphate in the stratosphere. The effects of volcanic emissions of sulfur dioxide on the stratospheric aerosol will be considered.

SUPPORTED BY U.S. National Science Foundation

1.0087, TRANSVERSE JET PLUMES

J. HALITSKY, New York University, School of Engineering, *New York, New York* 10453 (AT(30-1)3673)

The object is to obtain velocity and concentration distributions in the jet region of a chimney plume under several wind turbulence conditions. No full-scale and few wind tunnel experimental data are available for development of good mathematical models of this region of the plume. Tests will be run on a 30 m high stack in the atmosphere and a model of the stack in the wind tunnel. The tunnel air stream will be oscillated to simulate the low frequency components of the atmospheric spectrum of azimuthal fluctuations. Concentration tracers will be sulfur dioxide for both field and tunnel tests. Atmospheric turbulence will be measured by Vectorvane. Tunnel turbulence will be measured by constant temperature hot-wire anemometer. Spectrum analysis of long period oscillations will utilize a special frequency step-up system and a standard wave analyser.

Results: All experimental facilities and equipment have been completed. Field sample analysis procedures have been successfully applied in wind tunnel tests.

SUPPORTED BY U.S. Atomic Energy Commission

1.0088, SULFUR DIOXIDE OXIDATION

J. HAPPEL, New York University, School of Engineering, *New York, New York* 10453

The objective of this research is a study of the mechanism and kinetics of the catalytic oxidation of sulfur dioxide. The oxidation of sulfur dioxide is important as a means of conversion of this material in stack gases to sulfur trioxide which may then be removed as sulfuric acid. Although this problem has been studied extensively there is still no general agreement as to the mechanism involved. In the course of the present investigation we have found that the use of isotopic tracers such as 35S show great promise in better understanding this process. It appears that at low concentrations of sulfur dioxide the mechanism is different that at the higher concentrations normally employed in industrial conversion of sulfur dioxide for sulfuric acid manufacture. It would be desirable to extend these studies further employing super 18 O as a tracer to further narrow down the mechanistic sequence involved. Work during the final year of the current project will accomplish this. A versatile tool will then be available to screen various materials as possible catalysts which it is hoped will lead to techniques for economical conversion of sulfur dioxide in stack gases and their removal as sulfuric acid. Another application will be the establishment of the mechanism involved in oxidation of sulfur dioxide by atmospheric particulates to arrive at better understanding of the processes governing sulfur dioxide conversion in nature.

1.0089, THE USE OF LEAD-210 TO TRACE TRANSPORT PROCESSES IN THE FREE ATMOSPHERE

W.S. BROECKER, Columbia University, Graduate School, *Palisades, New York* 10964

The objective of the proposed research is to test the usefulness of lead-210, which has its source in the troposphere, as an atmospheric tracer for transport processes within the lower stratosphere and between the troposphere and the stratosphere.

The proposed measurements will indicate whether certain well documented atmospheric events, which occurred in 1963 and 1964, which should have affected the distribution of lead-210 did indeed so. These events were: 1. Changes in the circulation of the northern polar stratosphere in 1964-1965. 2. The advection of air into the lower polar stratosphere in January 1963 ('sudden warming'). 3. Changes in stratospheric circulation which apparently caused a rapid influx of bomb debris into the stratosphere in late 1963.

Measurements will be made on filter samples collected between 1962 and 1966 in the stratosphere and troposphere as part of Project Stardust. Four hundred filter samples will be analyzed by a procedure which involves the measurement of the daughter product polonium - 210. This procedure has worked successfully on a previous 200 samples.

SUPPORTED BY U.S. National Science Foundation

1.0090, STUDY BY CONTRACT THE INDOOR-OUTDOOR POLLUTION RELATIONSHIPS AT AN AIR-RIGHTS STRUCTURE AND A CANYON TYPE STRUCTURE

W. GILES, General Electric Company, *Schenectady, New York* 12305

Objective: Define the relationship of indoor-outdoor pollution concentration in an air-rights and canyon structure where people are exposed to high automotive emissions.

Approach: The contractor will measure concentrations of CO, total hydrocarbons, particulates, TSP and lead as well as traffic density and meteorological conditions at two districtly different constructed roadway-housing conditions during a heating and non-heating season.

Goal: Complete the study of the George Washington Bridge Apartments in New York City and begin study of a canyon-type structure also in NYC.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0091, ECOLOGY AND MARINE SCIENCES, METEOROLOGICAL AND AIR POLLUTION RESEARCH PROGRAM

M.E. SMITH, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The program is concerned with the structure of the lower atmosphere and to the behavior of gases and particles within it. The program is undergoing redirection toward study of both meteorology and dispersion on a 100-km scale. The site of the study will be the New York-Long Island area, and the emphasis will be on the understanding of the influence of urban structure and thermal characteristics on meteorological variables, and through the mechanism of wind structure and turbulence, on the dispersion of pollutants. Conversely, the behavior of pollutants will shed light on the meteorological processes. The Group effort associated with other Laboratory programs on CO2, SO2 and atmospheric aerosols will increase sharply also.

Results: Planning of the study in the transvective range has already begun, and preliminary studies based on the existing meteorological and air quality data will begin during FY 1970.

SUPPORTED BY U.S. Atomic Energy Commission

1.0092, SULFUR DIOXIDE DECAY

UNKNOWN, Brookhaven Natl. Lab., *Upton, New York* 11973

Field studies will be carried out Keystone and Honer City power stations (LAPPES Project sites)to describe the generation, transport,diffusion and chemical reaction of sulfur pollutants

emitted into the atmosphere from the tall (soft) stacks at the power generation facilities. Sulfur ratio (S32/S34) and other trace gases will be used to assess the residence time of sulfur compounds in the atmosphere.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0093, ASSIST OCS IN THE DEVELOPMENT OF COMPUTERIZED SYSTEM FOR PROJECTING MOTOR VEHICLE EMISSIONS AND SUPPLY ADJUNCT ANALYSES

J. BEATY, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop and maintain a computerized system for vehicle emissions on a nation-wide basis.

Approach: The emissions will be estimated by examining available statistics on vehicle distribution, projected travel requirements, and characteristics, vehicle speeds and other factors, and combine these with legislated or anticipated emission regulations. This system will allow the projection of motor-vehicle generated CO, HC, NOx, and particulates for the nation as well as selected regions.

Goal: Gather information on projected travel requirements, vehicle age and type, average route speed, and road conditions, and assist in the updating of previous projections.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0094, ODOR ISOPLETHS AND TRANSPORT MODELS

R.C. DICKERSON, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop isopleth models for odorants from various industrial sources.

Approach: Several techniques for deriving odor isopleths will be investigated. Initially, both the frequency and intensity patterns of odorants will be delinated. The area and population subjected to odorants will be determined so that impact in terms of social or economic response can be measured.

Goals: To develop a method for predicting areas subjected to odorants from various sources.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0095, PROVIDE INFORMATION ON EMISSIONS FROM NUCLEAR FACILITIES

G. DUGGAN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop and maintain information, statistics, and projections on emissions from nuclear facilities.

Approach: One person is assigned to Bureau of Radiological Health to begin to translate their information into a format compatible with NAPCA's emission reporting requirements.

Goal: Develop in-house capability to assess emissions from nuclear facilities.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0096, TESTING OF CONVENTIONAL AND EXPERIMENTAL OIL AND GAS BURNERS

R.H. HALL, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To establish critical destillate burner design parameters in pollutant emission.

Description: Test work will continue to evaluate commercially available burners used in domestic heaters, and will be extended to residual oil-fired burners used in commerical and industrial boilers. In addition to these conventional burners, studies will be made of distillate oil-fired prototype or experimental burners to define what design characteristics of parameters are critical in the emission of pollutants, such as nitrogen oxides and carbon particulate.

These studies will utilize various analytical techniques such as temperature and pressure Probes, thermal photography, high temperature pitot-tubes, and cold flow tracers to relate the burners dimensions to general flame characteristics, (i.e., temperature, turbulence, mixing, and atomization). These correlations will lead to design criteria which can be applied to control emissions from any distillate oil-fired burner and will be useful as a mode for studying burner design-emission levels in other fossil fuel-flame combustion systems.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0097, CHARACTERISTICS OF PARTICULATE EMISSIONS IN AUTO EXHAUSTS - DESIGN AND TEST SIMPLIFIED SAMPLING SCHEME

R. HERLING, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Current emphasis is on development of sampling and measurement technology to facilitate required studies and compliance testing. Several alternate sampling arrangements are being considered. Use of piezoelectric microbalance will be evaluated. Experiments will include size distribution and chemical analyses for important particulate components (Pb, Cl, Br, S, Fe, carbonaceous matter, etc.).

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0098, UPDATE NAPCA DATA FILE OF NATION-WIDE EMISSIONS

A. HOFFMAN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To provide current information on nation-wide emissions of the major air pollutants.

Approach: Compile statistics on motor vehicle travel, fuel consumption, refuse disposal, industrial activity, and other indicators of pollutant emissions such as degree of control. Using average emission factors, calculate emissions of SOx, particulates, CO, HC, NOx Pb, F, asbestos, cadmium, and nickel.

Goal: Re-issue 'NAPCA Data File of Nation-wide Emissions' publication for 1969.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0099, EVALUATION OF CONTRIBUTIONS OF VEHICULAR EXHAUST AND OTHER SOURCES TO ATMOSPHERIC LOADINGS OF POLLUTANTS IN THE N.Y.C. - N.J. AREA

S.L. KOPCZYNSKI, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Samples from tunnels and highways will be analyzed to serve as references for vehicular exhaust composition. These samples and previously collected air samples from various localities will include analyses for paraffins, olefins, aromatics, acetylene, CO, NO2, SO2, ozone and aldehydes. Mathematical and statistical tests will be made on data from the air samples to obtain estimates of source contributions (particularly vehicular exhaust), estimates of rates of decay of pollutants in the atmosphere, and evidence of transport of pollutants.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0100, ENGINEERING STUDIES RELATED TO THE TECHNIQUES AND INSTRUMENTATION USED FOR FUEL AND FUEL ADDITIVE EVALUATIONS

M.W. KORTH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Provide vehicles, dynamometer equipment, and operating personnel to support gasoline composition and additives studies. Analyze and report gaseous emission levels for CO, CO2, HC, NOX, and O2 as required.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0101, COMPLETE THE ENGLAND SMOKESHADE - U.S. PARTICULATE COMPARISON STUDY

R.E. LEE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To complete assessment of England Smokeshade Data as compared to U.S. measurements by hi-vol membrane filter, cascade impactor and tape samplers. This will permit equat-

ing health effects studies included in NAPCA's particulate criteria document.

Approach: After weighing particulate samples compare all data obtained with appropriate statistical analysis.

Goal: Complete the gravimetric analysis of collected samples, and perform statistical comparisons of smokeshade vs hi-vol and other particulate data. Prepare report, and subsequently, complete study to completely characterize samples taken. A report will be completed delineating the interrelationships of the U.S. and British particulate measurement methods to provide support for the NAPCA particulate criteria document.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0102, EVALUATION - CAVEN POINT OPEN PIT INCINERATOR

C.S. MANERI, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

This unit is a proto type subject to broad evaluation because of the flexibility of its design. A complete evaluation, including stack testing, will be undertaken in FY 71. Teams of other agencies, as well as involvement of Laboratory Branch, Engineering Branch and Federal Facilities Branch personnel will be used.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0103, URBAN RADIATION

J. PETERSON, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Radiation stations will be located in and around Raleigh, N.C. Each station will measure incoming and outgoing solar and terrestrial radiation. Broad-band spectral measurements of the incoming solar radiation will be attempted to isolate the absorption effects due to water vapor in the near infrared, and due to various pollutant gases (NO_2/O_3) in the ultraviolet.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0104, DATA ANALYSIS OF LAPPES

F. POOLER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Complete analyses of all available LAPPES - Keystone data to determine and describe: a. Sulfur dioxide plume concentrations distributions and plume behavior under selected weather conditions, i.e., stable and unstable cases. b. Sulfur dioxide concentrations distributions and frequencies in the vicinity of the Keystone Power Plant, i.e. a climatological appraisal. c. Representativeness and utility of standard observations for calculating ground-level concentrations.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0105, DETERMINATION OF THE EFFECTS OF FUEL ADDITIVES ON VEHICULAR EMISSIONS

J. SIGSBY, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

To determine the fate of fuel additives in combustion and, as required by the 1967 Clean Air Act, to determine their effects on other emissions from motor vehicles. In this year the emphasis will be on the effect of lead removal.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0106, DEVELOP AND MAINTAIN AN INFORMATION SYSTEM ON NATION-WIDE EMISSIONS FROM GASOLINE FUEL ADDITIVES

J. SMITH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To provide information on nation-wide emissions from gasoline fuel additives.

Approach: Through contact with gasoline manufacturers, and various taxation agencies, collect information on gasoline sales, and combine this data with additive concentrations which are supplied to DA under the registration program, to yield information on nation-wide emissions of the various chemicals. This activity also entails development of computer procedures for systematic data handling.

Goal. Produce first report on estimated quantities of pollutants released as a result of using gasoline fuel additives.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0107, DEVELOPING TIME-CONCENTRATION MATHEMATICAL MODEL FOR VARIOUS POLLUTANTS

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Using frequency distribution and other mathematical concepts, develop and up-date models describing air quality in representative AQCR's.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0108, EVALUATE FEASIBILITY AND NATURE OF A POSSIBLE PARTICULATE STANDARD FOR MOTOR VEHICLES

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

In addition to the reduced visibility brought about by the atmospheric photochemical interacton of HC and NOx in motor vehicle emissions, motor vehicle exhaust contains particulate matter which contributes directly to the particulate loading of the atmosphere. This is made up of the residues from additives introduced into the fuel, such as lead, as well as imcompletely combusted fuel itself. Solution of the problem could depend on the determination of the nature and relative importance of these various sources. For example, should the additive residue prove to be the important factor, it may be more appropriate to control its use in the fuel than its existence in the exhaust.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0109, DEVELOP ATMOSPHERIC MODELS

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Utilizing dispersion and kinetic mechanisms, develop models for relating emissions to air quality.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0110, EMISSION FROM THE PHOSPHATE FERTILIZER INDUSTRY - ANALYSIS OF SAMPLES

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Determine the applicability of sampling trains for measurement of gaseous and particulate fluorides. Analyze source samples including scrubber water and raw materials for content of fluoride, phosphate, and total particulates.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0111, EMISSIONS FROM THE PULP AND PAPER INDUSTRY - ANALYSIS OF SAMPLES

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Provide standard gases and delivery systems for calibration of gas analyzers. Analyze source samples for content of total particulates, Na, Ca, and SO_4. Develop and provide methodology and equipment for measuring odor dilution threshold. Test the applicability of the particulate sampling train to measurement of particulates in effluents from the lime kiln and other unit operations.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0112, SOURCE TESTS OF PULP AND PAPER MILLS

E.J. VINCENT, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Stack tests will be performed at 2 or 3 West Coast pulp mills. Particulate tests will be performed on recovery furnaces, lime kilns and smelt tanks. Ca, Na, SO_4 and total particulates will be

determined. Gaseous sulfur compounds will be analyzed and measured by a gas chromatograph, and other gas analyzers mounted in a mobile van. Odor dilution threshold will be determined and related to concentration of specific pollutant emissions.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0113, WRITE REPORT OF PULP AND PAPER STUDY
E.J. VINCENT, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Tabulation and analysis of questionnaire data will be completed and 3/4 of test results will be evaluated. Twenty-five percent of a first draft will be completed.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0114, MODEL RESIDUAL OIL COMBUSTOR
J.H. WASSER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To determine critical operating and emission parameters in a residual-fired boiler.

Description: The model heavy oil combustion system will be studied to determine the effects of various critical combustion parameters on air pollutant emissions. Those which will be varied are: air-fuel ratio, high temperature gas reaction intensity, fuel pre-heat temperature, and fuel composition. Fuel types rested will range from 02 light distillate through and including 06 residual oil. Air pollutant emissions measured will include: carbon monoxide, total gaseous hydrocarbons, sulfur dioxide, sulfur trioxide, nitric oxide, filterable and condensable particulate, and Bacharach smoke number. Flue gas concentrations of oxygen and carbon dioxide will also be monitored. The special burner designed for this model system will permit a wide range of air-fuel mixing turbulence conditions to be simulated and enable determination of the critical design parameter values in pollution control for heavy oil combustion burners. Later studies will investigate the NOx and carbon particulate control techniques, staged conbustion and flue gas recirculation.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0115, ATMOSPHERIC DUST AND MOLD SPORE STUDIES
L.J. SCHERMEISTER, U.S. Veterans Administration, Center, *Fargo, North Dakota* 58102

A five year study has been conducted on the atmospheric incidence of dust in mold spores in North Dakota and nine westerm counties of Minnesota. During this study at the Fargo station it was determined that all veterans who had worked in grain who were included in the study had done so only after serving their time in the armed forces. It was also noted that the amount of organic and inorganic material to which personnel were exposed was extremely high in and around the grain elevators.

Since it has been shown by several authors that these inorganic substances are not dissolved by lung fluids, this continuing study will develop a method to determine the type and amount of inorganic material on the sample slide by means of spectrographic analysis. The total amount of inorganic material at the seven stations in North Dakota and Western Minnesota has been collected on petroleum smeared glass slide. The slide will be washed with pertroleum ether into a small vial, and then the residue dissolved in concentrated HNO3 and diluted with a few cc of H2O and read in a flame spectrophotometer. This would determine inorganic Pb.,Hg., Ag.,P.,S.,etc.

Should any of the data reveal striking regionalization or distribution of any particulate matter of inorganic nature, an attempt could then be made to correlate it with veterans coming from these areas.

SUPPORTED BY U.S. Veterans Administration

1.0116, PILOT PLANT COMBUSTION TESTS OF LIGNITE AND WESTERN COALS
J.L. ELDER, U.S. Dept. of the Interior, Bureau of Mines, *Grand Forks, North Dakota*

The purpose of this project is to study lignite combustion problems, especially those relating to ash fouling in a 75 lb/hr pilot plant furnace and to develop engineering data which will help to alleviate the problems in commercial boilers; and concurrently, as feasible, to use the equipment to study stack emission problems in connection with air pollution.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0117, COMBUSTION TESTS OF LIGNITE AND WESTERN COALS
J.L. ELDER, U.S. Dept. of the Interior, Bureau of Mines, *Grand Forks, North Dakota*

It is the purpose of these tests to correlate operation of the pilot plant combustor with operation of commercial pc-fired equipment. Maintain close contact with electric generating plants burning lignite and other Western coals particularly those that are experiencing fouling problems.

To study ash fouling and air pollution problems relating to combustion of lignite and other Western coals. Tests will be run with a 75 lb/hr pilot plant furnace in an attempt to develop engineering data which will help alleviate problems being experienced in commerical boilers.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0118, KINETICS OF SULFUR-OXIDE FORMATION IN FLAMES
A. LEVY, Battelle Memorial Institute, *Columbus, Ohio* 43201

Kinetic processes in the H2S and COS flames are being examined and developed using flame microstructure techniques. The oxidation of H2S in flames appears to occur through several steps involving the sulfur- containing intermediates SH, S2, SO and SO. The latter three intermediates have been detected in mass spectrometric analyses of samples taken from H2S flames, and appear in the flames in the order given. Mass spectrometric data also indicate that H2O2 may be forming early in the flame reactions. An H2S oxidation mechanism consistent with the observed order of appearance of the intermediates in the flame is presently under consideration. Data from COS flame studies indicate the presence of a considerably smaller quantity and fewer number of intermediates in this flame. Additional flame probings are being carried out at the present time to further clarify the role of intermediates in COS flames.

Studies of the formation of SO3 in H2S and COS flames have shown that the formation of SO3 is pressure dependent in accordance with the three-body reaction SO2 plus O plus M equals SO3 plus M, the amount of SO3 increases with increasing pressure in the system. Attaching hydrogen to the sulfur atom in a fuel decreases the amount of SO3 formed in the system at a given pressure. O-atoms also tend to decrease the amount of SO3 formed in the system through the reaction, SO3 plus O equals SO2 plus O2. This reaction is significant in flames at pressures below 250 torr and at the higher temperatures encountered in the regions beyond the visible flame zone. Rate constants have been determined for the SO3-O reaction which gave an activation energy of 12.0 plus or minus 1.5 kcal/mole for the SO3-O reaction.

Next year's work will involve a detailed study of the oxidation of sulfur compounds in flames supported by dydrocarbon fuels such as CH4. This system will allow one to study sulfur oxidation processes under conditions more closely simulating those found in commercial firing units.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0119, 5 - YEAR BATTELLE COMBUSTION STUDY
D.L. LOCKLIN, Battelle Memorial Institute, *Columbus, Ohio* 43201

This study is established to determine the long range research program required to yield a thorough understanding of combustion processes and how they relate to air pollution emissions and their potential control. Since the current state of the air knowledge of combustion and how it relates to air pollution is not sufficiently developed, this project will encompass the gathering

of background information on combustion research which will be the basis for laying out a 5 year program to fill gap areas described.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0120, EFFECTS OF IMPROVED FUEL ATOMIZATION - VAPORIZATION AND MIXING ON EMISSIONS FROM MOBILE SOURCES
D.L. LOCKLIN, Battelle Memorial Institute, *Columbus, Ohio* 43201

Project objectives include laboratory verification of analytical data and carburetor design requirements developed under an FY 69 program with Battelle Memorial Institute. This will include determination of the interaction of fuel droplet size, manifold geometry, and system vaporization characteristics over a range of conditions existing in an automotive induction system. This information will then be used to select, design, and build a carburetor to meet the design requirements. FY 70 funding includes the development of methods for measuring induction-system mixture properties.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0121, TURBOPROPULSION ENGINE EXHAUST EMISSIONS INVESTIGATION
E.E. HIVELY, U.S. Air Force, Aerospace Propulsion Lab., *Dayton, Ohio*

Technical Objective: To investigate in a systematic way the combustion products emitted by Turbo-Propulsion engine systems which may contribute to pollution or contamination of the atmosphere. Both afterburning and nonafterburning systems will be examined.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0122, AN ENGINEERING STUDY OF LP GAS AS AUTOMOTIVE FUEL
J.R. ALLSUP, U.S. Dept. of the Interior, Bureau of Mines, *Bartlesville, Oklahoma*

Purpose: To obtain engineering data on the relationship between emission levels and engine adjustments using propane as fuel; to the extent possible to describe the potential and practical application of propane as automotive fuel for clean air requirements.

Method: Using propane as fuel, measure emissions from three vehicles representing, respectively, light-delivery, high production passenger, and general-utility categories. Obtain comparative data using three gasolines--(1) national average composition, (2) as preceding except with C sub 4 and C sub 5 olefins replaced with corresponding saturates, and (3) a prototype unleaded fuel. Conduct work at two temperatures, 20 degrees and 85 degrees F, and generate samples operating vehicles on a chassis dynamometer using simulated traffic cycle typical of city driving.

Achievements 1969-1970: Results not ready for reporting. Progress to be reported in the fall of 1970 and completed in the spring of 1971.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0123, EFFECT OF FUEL VOLATILITY ON AUTOMOTIVE EMISSIONS
B.H. ECCLESTON, U.S. Dept. of the Interior, Bureau of Mines, *Bartlesville, Oklahoma* 74003

Purpose: To determine the overall effect on vehicular emissions in changing volatility levels in the light end of motor gasoline.

Method: Evaporative losses from the fuel system of a fleet of vehicles are measured during operations typical of the vehicles' use. Tailpipe emissions are measured during the same period of use. Total vehicular emissions are related to the volatility of fuel with which the emissions are associated.

Achievements in 1968: Results showed that volatility reduction reduced both the quantitative total of exhaust and evaporative losses and the photochemical effect from these emissions. Replacing the olefin in the front end of the fuel with no change in volatility did not change the quantity of total hydrocarbon emissions but did reduce the photochemical effect of these emissions. The reduction in photochemical effect by olefin replacement was greater than the reduction from lowering fuel volatility to the lowest level considered in this study.

1.0124, PRODUCTS OF COMBUSTION OF DISTILLATE FUELS FOR MOTIVE POWER
R.D. FLEMING, U.S. Dept. of the Interior, Bureau of Mines, *Bartlesville, Oklahoma*

Purpose: To improve knowledge of the products of combustion from diesel and turbine engines using distillate-type fuels; to describe the interacting influences of fuel composition and engine parameters on smoke, odor, and other exhaust products that are objectionable as air pollutants.

Method: For the odor study, continue work on analytical proceduresto complex, isolate, and subsequently regenerate aldehydes. Continue the study of engine variables and fuel composition as factors governing the character and quantity of diesel emissions. Continue work on development of a procedure to measure photochemical reactivity of diesel emissions. When an acceptable procedure is realized, generate information as feasible on the reactivity of 'typical' diesel exhausts to better define the contributions of diesels to photochemically affected areas. Install a small gas turbine; using exhaust from this gas generator as sample, continue work adapting and refining procedures for turbine emission measurement.

Achievements 1969-70: A dynamic odor generator was built and produced gas carrying a good approximation to diesel exhaust odor. The carbonyls present in exhaust were shown to be largely the lower aliphatic aldehydes and aromatic aldehydes. Exhaust NOx was found significantly reduced with decreasing intake air temperature; up to 60 pct reductions in NOx emissions were realized with 20 pct recirculation of cooled exhaust; NOx and smoke emissions were strongly influenced by injection timing. None of the variables significantly reduced unburned HC or odor. Preliminary and highly tentative findings in a study of diesel exhaust reactivity show diesel exhaust and gasoline exhaust to have roughly comparable HC reactivities. Working with cooperators, aircraft turbine emissions were successfully measured; HC and RCHO emissions were found to be significant during the idle mode; NOx was the only emission of any consequence during the higher power modes.

1.0125, AIR & WATER POLLUTION PPBS-20-55-12 FUELS COMBUSTION RESEARCH
R.W. HURN, U.S. Dept. of the Interior, Bureau of Mines, *Bartlesville, Oklahoma*

Purpose: (1) To provide research and development on analytical methods and experimental methodology for studying abatement of air pollution related to hydrocarbon fuels usage in IC engines. (2) Through experimental research both in-house and in cooperation with industry and/or other agencies, to describe the characteristics of engine/fuel systems as they relate to air pollution problems and as they offer potential for air pollution abatement. (3) To provide a continually updated facility for research on air pollution associated with vehicular emissions.

Method: Experimental research is conducted on light hydrocarbons as automotive fuels for clean air requirements. Working with engines and vehicles representative of both current and near-future production, engine adjustments are determind for optimum balance of hydrocarbon, NOx, CO, and RCHO emissions using natural and synthetic gases as fuel. The safety hazard of a diesel engine operating in an unventilated mine is being experimentally studied. Testing is to determine rate at which the concentrations of toxic materials increase and levels to which they increase in case of ventilation failure in underground mine spaces. A project to survey emissions (HC, CO, and NOx from small utility engines (up to 50 cu.in.) is underway.

1. AIR QUALITY

Achievements 1969-70: Work with one fleet of vehicles using compressed natural gas was completed. HC emissions were about 0.7 gram/mile, CO emissions about . 6 grams/mile, and NOx emissions about 5.9 grams/mile. Emissio.. levels were largely unaffected by ambient temperature within the range 20 degrees to 90 degrees F. Analytical and engine and vehicle test facilities were updated to provide reliable measurements of emissions at the greatly reduced levels expected of mid- 1970 automobiles.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0126, EXPERIMENTAL METHODS FOR DETERMINING OXYGENATES IN AUTOMOTIVE EXHAUST
D.E. SEIZINGER, U.S. Dept. of the Interior, Bureau of Mines, *Bartlesville, Oklahoma*

Purpose: To determine those oxygenates that appear in significant quantities in automotive emissions.

Method: An experimental study is conducted to determine relative levels of carbonyl and noncarbonyl oxygenated hydrocarbons in automotive exhausts. Used as fuels are paraffinic, olefinic, and aromatic pure hydrocarbons and simple mixtures of these hydrocarbons that in the aggregate encompass the hydrocarbon range of full-boiling motor fuels. In generating exhaust samples, engine test procedures are used that simulate metropolitan city driving. Procedures are to be developed for converting carbonyl oxygenates present in IC engine exhausts into oxime derivatives for subsequent analysis of resultant derivatives by gas chromatography.

Achievements 1969-70: Procedures were developed to determine the oxygenated hydrocarbon derivatives in exhausts from SI engines using fuels of simply hydrocarbon mixtures. These analyses included virtually all oxygenates whereas procedures now commonly in use measure only nonaromatic aldehydes of relatively low molecular weight. Several carbonyl and noncarbonyl oxygenates were found.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0127, CHARACTERISTICS AND PHOTOCHEMICAL REACTIVITY OF FUEL COMPONENTS AND COMBUSTION PRODUCTS
G.P. STURM, U.S. Dept. of the Interior, Bureau of Mines, *Bartlesville, Oklahoma*

Purpose: To further define the chemical nature of products of combustion of hydrocarbon automotive fuels and experimentally to determine interrelationships between the emissions that result from fuel usage and their photochemical reactivity in the atmosphere.

Method: Expose diluted auto exhaust to photoirradiation and observe chemical and physical changes that occur in the mixture being photoirradiated. Measure total hydrocarbon, NOx, RCHO, CO, CO2, H2, and O2; determine hydrocarbon composition by GLC. Express reactivity measurements in terms of rate-of-NO2 formation and yields of oxidant, PAN and like compounds, and formaldehyde. Measure visibility reduction by light scatter.

In parallel obtain emissions data on fuels of widely varied composition using automotive equipment representing current and proposed production. To the extent possible relate fuel composition, emission composition, and exhaust gas reactivity.

Achievements 1969-70: Optimum HC and NOx concentration ranges for specified air-quality levels were established. A study of the contribution of aldehydes to reactivity of automotive exhaust suggested that formaldehyde acts synergistically to yield reactivity levels that are higher than expected.

1.0129, RESEARCH INITIATION - PHOTOOXIDATION IN HYDROCARBON-NITROGEN OXIDE SYSTEMS: A CHARCTERIZATION OF REACTOR WALL EFFECTS
B.L. CRYNES, Okla. St. Univ., School of Engineering, *Stillwater, Oklahoma* 74074

This purposed research is directly related to several important problems of air pollution and environmental control. Recent studies have been reported which involve photooxidation of hydrocarbon-nitrogen oxide systems as a laboratory simulation of certain conversions associated with atmospheric 'smog' reactions. In the reaction systems containing both reactants and products, reactor wall effects are known to occur. To obtain meaningful results from studies of the chemical aspects of these photooxidation reactions, the influnece of the reactor walls must be defined and characterized with respect to the complex reactions within the reactor boundaries. A systematic study will be initiated to define and characterize the effects and influences of reactor wall material and wall conditions of photochemical oxidation of olefins. Studies of the propylene-nitrogen oxide system will be conducted in a recycle-loop reactor designed to carefully control temperature, irradiation, reaction time, and mixing effects.

1.0130, KINETICS OF NITRIC OXIDE AT HIGH TEMPERATURES
R.A MATULA, Drexel University, School of Engineering, *Philadelphia, Pennsylvania* 19104

It has been shown that once NO is formed in the combustion process it remains fixed or frozen during subsequent portions of the power cycle, and hence essentially all NO generated during the high temperature combustion process is exhausted to the atmosphere. Therefore an understanding of the formation kinetics of NO is of major importance, and efforts directed toward the control of NO formation process must be logically preceded by an understanding of the chemical mechanism for NO formation. The overall objectives of this research project are to determine the mechanism and evaluate the temperature dependence of specific rate constants for nitric oxide production both in the absence and presence of hydrogen and hydrocarbons. These results will be subsequently utilized to suggest modifications of the combustion process which can be effectively utilized to minimize nitric oxide production.

Presently the decomposition of nitrous oxide is being studied in the temperature range 1000 to 1800 degrees K. The experiments are being carried out in a single-pulse shock tube, and the temperature dependence of a number of elementary rate constants are being evaluated. An experimental program in which both hydrogen and hydrocarbons are added to the system in order to determine the importance of H2, H2O, H, OH and hydrocarbons on the formation of oxides of nitrogen in combustion systems will also be carried out under auspices of this grant.

1.0135, ANALYSIS OF CHEMICAL COMPOUNDS IN AN URBAN AEROSOL
J.O. FROHLIGER, Univ. of Pittsburgh, School of Public Health, *Pittsburgh, Pennsylvania* 15213

The objectives of this investigation are (1) to establish the elemental composition of aerosols in the Pittsburgh air basin, (2) to identify the chemical compounds present in these aerosols and (3) to determine if the information obtained in (1) and (2) can be applied to the identification of the various sources of air pollution in the air basin.

The purpose of establishing these objectives is to determine the potential health hazards of the chemical compounds found in an urban aerosol and to see if these data can be used as guides to effectively control the quality of the air environment of the general population.

This investigation will utilize a variety of analytical techniques particularly gas chromatography, microcolumn chromatography, thin layer chromatography, thermal gravimetric analysis, differential thermal analysis, differential thermal gravimetric analysis, and microcoulometry. These techniques will be used separately and in combination to yield the necessary analytical data to establish the elemental and chemical composition of suspended particulate matter.

1.0136, MODELLING POLLUTANT CONCENTRATIONS
W.J. MOROZ, Penn. State University, Center for Air Env. Studies, *University Park, Pennsylvania* 16802

Maximum concentrations of pollutants develop in urban centers when local or mesoscale meteorological factors strongly influence, and perhaps dominate, the transport and diffusion patterns of the contaminants. Time varying numerical models for mesoscale flow systems and models for pollutant distributions of a static nature have been developed which provide reasonable ability.

In this work numerical mesoscale flow models and dispersion models are being modified and the separate models are being melded to achieve a quazi-dynamic predictive model for pollutant concentrations over an urban area when large scale flow patterns are weak. The effectiveness of representing an urban area as a virtual point source for predicting downwind concentrations of contaminants at some distance from the source to determine the effect of one urban center upon another is also being investigated.

1.0137, TRACE METALS AND HALOGENS IN THE ANTARCTIC ATMOSPHERE
R.A. DUCE, Univ. of Rhode Island, Graduate School, *Kingston, Rhode Island* 02881

It is proposed to study (1) the atmospheric particulate concentration of trace metals (V, Al, Cu, Pb, Mn, Fe, and Ni) in three Antarctic locations and compare the values wth other similar simultaneous measurements made in Hawaii and at various north and south Atlantic Ocean stations, and, (2) to collect particulate and gaseous samples of halogens (I, Br, Cl) in order to study the effect of a large land mass on atmospheric gaseous halogen concentrations. Measurement of concentration and ratio of concentration of atmospheric pollutants will help determine the N-S transport of urban air pollutants and determine the extent to which northern hemisphere continental source particulate matter is penetrating the Antarctic continent. The personnel have more than 10 years continuous experience in this and related studies of atmospheric chemistry. The analysis will mainly use the techniques of neutron activation analysis and atomic absorption spectrophotometry, the facilities and tools for which are available at Kingston, Rhode Island and which will not necessitate the introduction of any radio active materials into the Antarctic. The contribution of the sea, as well as that from urban areas, to the trace metals will be determined by means of ratio determinations. Changes in procedure should result in new low level detection limits. In addition to the Antarctic measurements three scientists will make halogen and trace metal concentration measurements at least two New Zealand station.

SUPPORTED BY U.S. National Science Foundation

1.0138, CONTINENTAL TRACE ELEMENT AIR POLLUTION IN HAWAII
R.A. DUCE, Univ. of Rhode Island, School of Oceanography, *Kingston, Rhode Island* 02881

Atmospheric particulate samples are being analyzed for the trace metals Na, Mg, Ca, K, Sr, Pb, Cu, V, Al, Mn, Fe, Co, Ni, and Zn by a combination of atomic absorption spectrophotometry and neutron activation analysis. Samples are collected on Delbag polystyrene filters using high volume pumps from a 20 meter tower on the windward coast of Oahu, Hawaii. Samples have also been collected from ships over wide areas of the north Pacific Ocean.

The metals Pb, Cu, V, Al, and Fe have considerably higher concentrations in marine air than would be expected if their source were the sea. This has been determined on the basis of the

atmospheric Pb/Na, Cu/Na, etc. ratios, assuming all the Na comes from the sea. There is a strong possibility that the source for the excess amount of these metals in marine air is the continents, and for some of them it may be air pollution. During the coming project year samples will be collected over the south Atlantic Ocean and from Antarctica for comparison with northern hemisphere concentrations of these elements.

1.0142, AREA SOURCE DIFFUSION MODELLING
F.A. GIFFORD, U.S. Dept. of Commerce, Air Reso. Atm. Turb. Dif. Lab., *Oak Ridge, Tennessee* 37830 (AT(40-1))

In FY 1970, using continuity principles, a method for calculating ground level concentrations of pollutants emitted from surface area sources was developed. The method is sufficiently simple that a digital computer is not necessary. In FY 1971 the area source diffusion model will be further studied and applied to a variety of problems, including the diffusion of heat over an urban area.

Results: In FY 1970 the model was tested using source data from several cities. The resulting ground level concentrations were in good agreement with oservations and the predictions of much more complicated models. In FY 1971 the predictions by this model will be compared with the predictions of other models, using a standard set of source data and observed concentrations.

SUPPORTED BY U.S. Atomic Energy Commission

1.0143, PLANETARY BOUNDARY LAYER STUDIES
F.A. GIFFORD, U.S. Dept. of Commerce, Air Reso. Atm. Turb. Dif. Lab., *Oak Ridge, Tennessee* 37830 (AT(40-1))

The distribution of winds, temperatures, and turbulence in the air over urban areas is being studied using the techniques of simple dimensional analysis and by solving the equations of motion and continuity with a digital computer. The reaction of constant density balloons to sinusoidal vertical air motion is being investigated by solving the equation of motion for the balloon. The role of the eddy dissipation rate in the spread of small smoke plumes is being determined by means of dimensional analysis of the problem and an experiment in which a small plume is released from a meteorological tower. In FY 1971 our model for diffusion from area sources will be used to investigate effects of changes in surface heat, moisture and momentum fluxes from urban areas. The computer model of three dimensional flow over an urban area will be further tested and results obtained for a variety of upstream boundary conditions.

Results: Several empirical relations describing the variation of winds and temperatures over urban areas were derived. The numerical model of the urban boundary layer was tested and will yield results shortly. The analysis of balloon response was completed, indicating that balloons are often out of phase with the air motion.

SUPPORTED BY U.S. Atomic Energy Commission

1.0144, NUMERICAL STUDIES OF TURBULENT FLOW
F.A. GIFFORD, U.S. Dept. of Commerce, Air Reso. Atm. Turb. Dif. Lab., *Oak Ridge, Tennessee* 37830 (AT(40-1))

Continued work on modelling the effect of terrain, buildings, radioactive decay and vertical meteorological parameters on the concentration and deposition of material downwind from an effluent source. Primary emphasis is on using the rather coarse vertical data obtained routinely from radiosonde data for the meteorological parameters.

Results: Preliminary models have been tested successfully.

SUPPORTED BY U.S. Atomic Energy Commission

1.0145, ATMOSPHERIC DIFFUSION STUDIES - LIDAR PLUME STUDY
F.A. GIFFORD, U.S. Dept. of Commerce, Air Reso. Atm. Turb. Dif. Lab., *Oak Ridge, Tennessee* 37830 (AT(40-1))

The objective of this study is to obtain data on the detailed structure of smoke plumes as they emerge from the Bull Run Steam Plant stack. Also, to obtain 'mixing depth' statistics for the Oak Ridge area. The use of a 'Lidar' in a fixed location, for several years, if necessary, to obtain detailed plume data is unique. Moreover, when additional power units are installed at the steam plant, their effluents will add to the burden of effluvium emitted from a single 800 ft. stack. The 'bench mark' studies now under way will be compared to the altered dynamics of the future plume.

Results: A 5 Joule laser radar has been assembled and tested. Studies of stack behavior have already begun.

SUPPORTED BY U.S. Atomic Energy Commission

1.0146, PLUME RISE AND FUMIGATION MODELLING IN A TANK
F.A. GIFFORD, U.S. Dept. of Commerce, Air Reso. Atm. Turb. Dif. Lab., *Oak Ridge, Tennessee* 37830 (AT(40-1))

The objective is to model the rise, spread, and subsequent diffusion of vertical plumes with both initial momentum and buoyancy. This will be done for calm conditions and various stratifications of the ambient fluid; later, convective motions will be induced to simulate the atmospheric mixing layer. These data should fill in some gas in existing plume rise data and, for the first time, provide some empirical basis for reasonable models of diffusion in nearly calm conditions, a situation that is becoming in-

creasingly critical as larger sources of emissions are built. The experiment is to be carried out in a 6 ft. by 6 ft. by 2.5 ft. deep tank, filled with water with a vertical salinity gradient to achieve stratification. The plume will be a hot, dense saline solution introduced through an inverted 'stack.' Dye will be added for cinematography using an overhead camera and a mirror mounted on the one side of the tank which is transparent. Conductivity probes will measure salinity and thermohm devices will measure the plume concentration, using temperature as a tracer.

Results: The tank, two auxiliary storage tanks, and plumbing with solenoid valves activated by float contacts have been built, allowing automatic filling of the main tank with several types of preset density profiles, including a linear one.

1.0149, REDUCTION OF POLYCYCLIC AROMATIC HYDROCARBONS

R. LONG, Univ. of Birmingham, *Birmingham, England, United Kingdom*

It has been known for many years that 3.4 -benzopyrene is a potent carcinogen and that some other polycyclic aromatic hydrocarbons are also carcinogenic. Such hydrocarbons are associated with smoke or particulate carbonaceous matter resulting from the incomplete combustion of fuels in heating plants or in engines (e.g. diesel smoke). Whilst cigarette smoking is a most important causal factor in lung cancer there also appears to be an air pollution factor since the frequency of this disease is higher in urban than in rural areas. (cf.Hoffmann and Wynder. Nat. Cancer Inst. Monograph No.9 61 (1962) and Truhaut. Proc. European Conference on Air Pollution, 89 (1964). The two factors may act in association. The potential danger of foodstuffs contaminated by carcinogenic air pollutants must also be recognized. Thus, Grimmer, Erdol u. Kohle 19, 578, (1966) has reported a surprisingly high content of 3.4-benzopyrene in certain vegetables as a result of air pollution.

A considerable amount of work has been carried out by Badger & his associates on the mode of formation of 3.4-benzopyrene during hydrocarbon pyrolysis but comparatively little has been published on the mode of formation of polycyclic aromatics during incomplete combustion in flames. Our work (see report) indicates that in flames pyrolysis processes appear to be responsible for their formation. Such processes are known to be influenced by catalysts and additives and further work is proposed to find out more about them and to attempt to reduce the formation of polycyclic aromatics during flame combustion. The combustion of liquid-fuels - when the fuel is 'atomized' in furnaces or diesel engines probably takes place largely in the form of a diffusion flame rather than as a pre-mixed flame where fuel and oxidant are homogeneously mixed prior to combustion. Consequently attention will be paid to both pre-mixed and diffusion flame combustion. Modern analytical techniques such as programmed temperature gas chromatography, thin layer chromatography and mass spectrometry will be used to investigate the pyrolysis reactions in the presence and absence of additives. Improvements will be sought in these analytical methods (for polycyclic aromatics in particular).

1.0152, UTAH ATMOSPHERIC WATER RESOURCES (THE WASATCH WEATHER MODIFICATION PROJECT)

G.W. REYNOLDS, Utah State University, Utah Water Research Laboratory, *Logan, Utah* 84321

The purpose of this study is to quantify the effects of cloud seeding on the winter snowpack in the Wasatch Mountains in Utah. Initially, at least, the seeding is to be with silver iodide from two mountain top and two valley generators, along the Wasatch Front, near Ogden. The evaluation is to be based primarily upon data from 150-200 telemetering precipitation gages. Approximately 40 of these stations are to be in operation during the 1967-68 winter. These measurements are to be supported with radar and special radiosonde observations.

Support studies in several areas are required: silver iodide background and plume nuclei studies; inadvertent cloud seeding by air pollution; precipitation analysis for silver and iodine; time and space synoptic climatology-cloud-precipitation studies; and hydrologic studies. These support studies have only been started. The bulk of the effort thus far has been on the development, adaptation, manufacture, and installation of the telemetering system (remote stations and terminal readout system).

The evaluation system will involve the comparison of natural and seeded precipitation patterns. Variations in both time and space will be considered. Both target versus control and seeded versus unseeded comparisons are to be made. Non-parametic statistical significance tests will be applied.

1. AIR QUALITY

1.0154, ATMOSPHERIC DIFFUSION AND TURBULENCE
S.K. KAO, Univ. of Utah, School of Mines, *Salt Lake City, Utah* 84112 (AT(11-1)-1585)

The investigation of space-time distribution and spectra of the kinetic energy of the large-scale atmospheric motion in the Northern Hemisphere will be extended to the Southern Hemisphere.

The investigation of the cospectra and cross-correlation of the components of the turbulent velocity in the Northern Hemisphere will be extended to the Southern Hemisphere.

The investigation of the space-time distribution and cospectra of the meridional transport of sensible heat in the Northern Hemisphere will be extended to the Southern Hemisphere.

This research will provide information which is useful for the prediction of air pollutants, particularly the radioactive debris in the atmosphere.

Results: The wavenumber-frequency spectra of the kinetic energy and cospectra of velocity components of the large-scale atmospheric motion in the Northern Hemisphere at 100, 200, and 500 mb, at 20, 40, 60 and 80N, show a definite spectral domain of wave activities in the atmosphere. The spectral domain is oriented from a region of low wavenumbers and low frequencies to a region of high wavenumbers and negative frequencies designated for waves moving from west to east.

SUPPORTED BY U.S. Atomic Energy Commission

1.0155, AIR POLLUTION IN TOPOGRAPHICAL DEPRESSIONS
S.K. KAO, Univ. of Utah, School of Mines, *Salt Lake City, Utah* 84112

Air pollution in both cities and suburban areas are affected by local topographic features, urban complexes, thermal stratifications, and the various scales of motion in the atmosphere. The objective of the proposed project is to estimate the amount of pollutant emission and to determine the meteorological and environmental factors for the transport and diffusion of te pollutants in valleys and other depressions. Included in the general description 'other depressions' are mountain canyons and 'metropolitan canyons,' i.e., the streets of the business districts of large metropolises.

A wide range of meteorological conditions will be studied, but emphasis will be given to the inversion and stagnation periods in which a stationary high pressure presides over depressions. It is known that the blanket effect of temperature inversions is the most effective mechanism for trapping air pollutants in topographical depressions.

Three investigative techniques will be used simultaneously. Analytical and experimental models will be constructed of simple depressions and field studies will be conducted to provide a guide for the analytical modeling and experimental simulation. The capabilities of meteorologists will be coupled with the expertise of engineers involved with geophysical fluid mechanics and convection.

1.0156, COMPOSITION AND DISTRIBUTION OF FOREST FIRE SMOKE
D.F. ADAMS, Washington State University, School of Engineering, *Pullman, Washington* 99163

This is to be a three-phase laboratory, field, and theoretical study of the air pollution potential from the prescribed fires of forest fuels conducted as an integral part of forest land management. The laboratory study will quantitatively and qualitatively define the range of solid and gaseous combustion products produced from the burning of two major fuel species (fir and larch). Fuel variables such as volume and moisture by size classification will be considered in establishing the anticipated range and types of combustion products. The field phase will encompass extensive sampling of the combustion products (and their measurable effects) from thoroughly documented prescribed fires. The theoretical phase will attempt to relate the field-measured pollutants and the quantities of pollutants predicted from the laboratory studies through mathematical models of atmospheric diffusion phenomenon.

The practical objective is to define the range of prescribed fire environmental conditions which will minimize air pollution and achieve the objectives of forest management.

This research proposal represents a cooperative program with personnel of the Northern Forest Fire Laboratory and Region I Forest Administrators.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0157, ANALYSIS OF THE ATMOSPHERIC PHOTOCHEMICAL REACTION PRODUCTS OF TERPENES
R.A. RASMUSSEN, Washington State University, School of Engineering *Pullman, Washington* 99163

The major objective of the proposed investigation is a laboratory and field study of the air chemistry fate of the volatile terpenes emitted into the atmosphere by plant foliages. This study will make measurements on the reaction products, rate of reaction and the carbon balance for different photochemical systems in respect to the specific terpenes studied. Atmospheric photochemistry studies on terpenes and even isoprene are very limited. The potential sources of reactive hydrocarbon-terpenes (alpha-pinene, beta-pinene, limonene) is not solely limited to conifer tree species: many broadleaf tree species in the United States are active releasers of the highly reactive hemiterpene; isoprene. Therefore, it is appropriate to initiate a research project to obtain data leading to an understanding of the air pollution potential and natural atmospheric chemical fate of such ubiquitous, naturally occurring reactive hydrocarbons in our global atmosphere.

A practical objective will be to determine and compare the reaction products of terpenes formed in simulated atmospheric irradiation chambers with the natural atmospheric photochemical products associated with plant foliages and the ambient atmosphere.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0158, FALLOUT PHENOMENOLOGY
W.E. DAVIS, Battelle Memorial Institute, *Richland, Washington* 99352 (AT)

The studies are designed to describe the history of atmospheric debris, including fallout from nuclear devices. A reliable technique for following debris in the lower atmosphere under diabatic conditions is needed to determine consequences of nuclear accidents as well as to follow fallout from nuclear devices under various atmospheric conditions. Methods for prediction of trajectories are also needed.

Techniques are to be developed for estimating effect on air motions from diabatic conditions such as are produced by precipitation, surface heating, terrain effects, and radiational heating and cooling. These must be tested against observations of contaminants, tracers or conservative properties of the atmosphere. From these results fallout models can be modified to produce a procedure for predicting transport and areas of anomalous dosages at the surface. These improved techniques will lead to a general macroscale fallout model including some mesoscale effects which can follow and predict the path and deposition of debris under various atmospheric and terrain conditions.

Results: A case study of Phoebus IB EP-IV, February 1967, was completed with the diabatic trajectories successfully describing the transport of radioactivity. A computerization of a radiation model has been completed and used both in calculations for a case study as well as for a comparison study with other models. Further studies on the identification of effects altering transport

has been made with the result that case studies included an attempt to estimate downward mixing layers from analysis of radiosondes.

SUPPORTED BY U.S. Atomic Energy Commission

1.0159, ATMOSPHERIC DIFFUSION, DEPOSITION, AND TRANSPORT PHENOMENA

P.W. NICKOLA, Battelle Memorial Institute, *Richland, Washington* 99352 (AT)

The study is directed toward understanding the behavior of gaseous and particulate material released to the atmosphere from atomic energy installations. The history of such materials as they are diffused by tubulent action, transported by various scales of atmospheric motions, and deposited on the ground and vegetation are investigated under various meteorological conditions and the influence of varying surfaces. An extensive field program is employed, in which atmospheric tracers are released and subsequently sampled simultaneously at hundreds of locations on a geometric grid extending to 26 km from the release point. Relationships between the diffusing materials and measurable atmospheric parameters are established. Findings are desirable to establish design criteria for effluent decontamination, for control of immediate and potential hazards arising from process operations, and as basic information for advisory groups in evaluating the adequacy of protective programs.

Results: Analysis of real-time data resulting from ground-level releases of Kr85 gas was undertaken during the past year. It was found that concentration fluctuations in diffusing plumes were greater in intensity and frequency than was expected. To distances of 800 m from the release point of puffs, it was found that regardless of stability, puff length sigma sub x was greater than puff width sigma sub y which in turn was greater than puff height sigma sub x.

1.0160, RADIOACTIVE FALLOUT RATES AND MECHANISMS

J.A. YOUNG, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The objectives of this study are to determine the distributions of radionuclides and trace elements in the atmosphere and the rates and mechanisms by which airborne particulates are transported to and deposited on the earth's surface. Studies of the chemical and radiochemical composition of atmospheric aerosols from ground level to maximum attainable altitudes are made to determine the rates and mechanisms by which airborne radionuclides become attached to the aerosol, the origin and chemistry of the host aerosol and the rates and mechanisms of the mixing and scavenging processes. Vertical profiles of concentrations are measured in the atmosphere and the sea near the surface. The data and the concentrations in precipitation are used with vertical profiles and variations of wind, temperature, and humidity to determine the effects upon the vertical flux of radionuclides, the flux across the sea surface, and the vertical flux in the surface layers of the oceans.

Results: The production rates of Cl-39, Cl-38, S-38, Cl-34m, Mg- 28, Na-24, and F-18 produced by spallation of Ar-40 with cosmic rays have been determined for the first time and used as tracers of precipitation and short-term atmospheric mixing processes. During the experimental phase of the Barbados Oceanographic and Meteorological Experiment, the concentrations of Be-7 and several nuclear-weapons- produced radionuclides were measured in air, seawater, and rain samples. Nineteen elements have been measured on filters and in rainwater to establish the gradient of several trace elements from troposphere through lower stratosphere.

SUPPORTED BY U.S. Atomic Energy Commission

1.0161, FLAME RETARDANTS AND AIR POLLUTION FROM SLASH BURNING

R.C. CORLETT, Univ. of Washington, School of Engineering, *Seattle, Washington* 98105

A research program is proposed for investigating the effect of flame retardants on air pollution due to burning of logging slash. With the cooperation of the U.S. Forest Service, a matrix of controlled field scale experimental fires will be held at a site near Bend, Oregon in the Deschutes National Forest.

Because of the difficulties inherent in achieving scientific control in field burning experiments, a major objective is the development and evaluation of experimental procedures. In addition, it is expected that there will be obtained substantive new data relating to the quantity of pollutant formed, the mechanism of its formation in the fire, and its short range dispersion in the atmosphere. This new information will be compared with suggestions based on laboratory scale research and will be sharpened by new laboratory scale experiments as appropriate.

This research program will suggest improved procedures for minimizing air pollution due to slash burning. A rational and efficient research program will be formulated for execution on a longer time scale than this proposed one year program.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0162, THE CONTRIBUTION OF FOREST FIRES TO ATMOSPHERIC POLLUTION

L.J. FRITSCHEN, Univ. of Washington, School of Forestry, *Seattle, Washington* 98105 (WO2102)

OBJECTIVE: Determine the amount of fuel consumed in the burning of logging slash and the combusion products that contribute to air pollution. To determine the atmospheric and fuel moisture conditions affecting efficiency of combustion and the distribution of gaseous and particulate pollutants.

APPROACH: Determine the weights of different kinds and sizes of fuel components. Measure moisture contents at time of burning. Measure residual weights and moisture contents after the fire. Develop sampling designs to distinguish between ambient air conditions and those induced by the fire itself. Determine vertical and horizontal wind components, degree of stability and wind shear. Determine the kinds, densities, fallout patterns and horizontal and vertical trajectories of various pollution components.

PROGRESS: Investigated the relationships between slash burning and air pollution with broadcast, and laboratory fires. Tested hypothesis that incomplete combustion and greater pollutant emissions result from low temperature, broadcast fires. Investigated burning characteristics and the gaseous hydrocarbon and particulate emissions from the three types of experimental fires. Results suggest that broadcast fires can be modeled in the labortary with respect to burning characteristics and gaseous and particulate emissions from different fuel density, packing quality and method of ignition. These experiments indicate that the air pollution from slash burning can be minimized with a high energy fire under conditions favorable for rapid atmospheric dispersion. Also, results showed that the concentration of gases and hydrocarbons dilluted rapidly to ambient values. Particulate emissions in the smoke plume were high, but decreased in 20 km. to values found over Seattle. Additional significant findings and developments are: flight tested the airborne version of the integrating nephelometer; developer air samplers, capable of operating without power, to collect air samples over a period of time; and found the peak frequency of flame speeds to be 3 m. sec.

1.0163, KINETICS OF NITROGEN-OXIDE AUTOMOTIVE POLLUTION

A. HERTZBERG, Univ. of Washington, School of Engineering, *Seattle, Washington* 98105

A sequence of processes in the Automotive Pollution Shock Tube closely simulates automotive engine cylindar operation. We are investigating the formation and decomposition of oxides of nitrogen in this apparatus.

A gasdynamically actuated endwall sampling system with time resolution of 0.1 msec has been developed. This technique, in conjunction with absorption spectroscopy will be used to monitor nitrogen oxide concentration in the test section. An advanced chemical monitoring technique, utilizing a frequency selective carbon monoxide laser is also under development.

This system will be used to make decisive measurement of nitrogen oxide production as a function of operational variables appropriate to engine design and adjustment.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0164, CHEMISTRY OF SULFUR IN HOT COMBUSTION GASES

C.B. MEYER, Univ. of Washington, School of Arts, *Seattle, Washington* 98105

Study of the oxidation and reaction of SO2 and other combustion gases in pure form and in mixture. Reactions of hot combustion gases with atmospheric gases. Absorption of SO2 and NXOY on solid catalysts. Recovery reactions to re-activate catalyst and transform SO2 and sideproducts into useful or harmless, non-polluting chemical compounds. A second goal is the study of chemical reactions of SO2, NO2 and CO2 in their lowest excited triplet states Tl.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0165, INFRARED SPECTROSCOPIC ANALYSIS OF TRACE POLLUTANTS

C. KARR, U.S. Dept. of the Interior, Bureau of Mines, *Morgantown, West Virginia*

Purpose: Identify and determine the amounts of the individual minerals and inorganics in various coals burned for electric power generation and burned in experimental fluidized-bed combustion equipment, using low-frequency and vacuum far infrared spectrometry. Similarly analyze the mineral and inorganic particulate pollutants emitted to the atmosphere from industrial equipment, using limestone injection with these coals, and from fluidized-bed equipment burning these coals. Correlate the kinds and amounts of mineral and inorganic pollutants with the minerals and inorganics in the various coals, and with the various operating conditions used during combustion of these coals.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0166, COMBUSTION PROCESS ANALYSIS

H.K. NEWHALL, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

There are two broad objectives for the proposed research. These are stated as follows: 1. It has been established that the formation and subsequent emission of nitric oxide and carbon monoxide by automotive combustion processes are controlled by chemical kinetics of the combustion and post combustion processes. One of the objectives of the proposed research is the continuing investigation of the basic kinetic mechanisms responsible for formation of these undesirable chemical species under conditions of combustion in automotive propulsion systems. 2. Results of basic investigations performed during the preceding period of this project have resulted in a concept in combustion chamber design which holds promise for reduction of air pollutant emissions from automotive power plants. It is proposed to continue study of this concept with the objective of systematic optimization of chamber design from the standpoint of exhaust emissions and engine performance.

1.0167, RADIATIVE PROPERTIES OF AEROSOLS IN THE STRATOSPHERE

J.A. WEINMAN, Univ. of Wisconsin, Graduate School, *Madison, Wisconsin*

The objective of the research is to continue to study the radiative properties of the stratospheric aerosol by means of theoretical studies, experiments and the analysis of observational data. The program is divided into several problem areas: (1) flights of several radiometersondes with simultaneous hygrometersonde ascents to check if the aerosol contains significant quantities of water; (2) measurement of the spectral dependence of the infra-red complex index of refraction of solutions expected in the stratospheric aerosol; (3) analysis of the spectral radiance of the stratospheric aerosol using data obtained in (2); (4) compilation of data describing the global aerosol distribution and (5) simultaneous aerosol measurements by lidar and radiometersonde at various latitudes in both hemispheres aboard ships enroute to the Antarctic.

1.0169, CHRONIC LUNG DISEASE IN NEW GUINEA POPULATIONS

C.R. BLACKBURN, Univ. of Sydney, *Sydney, Australia*

The prevalence and incidence of chronic non-tuberculous lung disease in some native populations in Papua and New Guinea is being determined by epidemiological methods. Complete subpopulations, clans or village groups, are surveyed by standard methods at intervals of 1-3 years and particular emphasis is being placed on serial changes in peak expiratory flow rates. The subpopulations selected are relatively isolated, with little urban contact, and in both coastal and highland districts. The elucidation of the nature of the disease and its relationship to chronic cor pulmonale is being sought by studying the clinical course, changes in respiratory function and pathological changes in the lungs of selected natives with chronic lung disease. Respiratory function studies include measurement of lung volumes, blood gas tensions, diffusion capacities, and ventilatory function. Etiological factors, such as infection, air pollution, and sensitization to fungal products or visceral larval migrans, are being studied. The elucidation of this disease in New Guinea may lead to its prevention there as well as in other non-industrialized Asian countries. The etiological factors of the disease are relevant to chronic non- tuberculous lung disease in industrialized countries, such as the U.S.A., U.K. and Australia, especially since air pollution is an entirely different problem in New Guinea.

1.0170, BIOLOGICAL EFFECTS OF GASEOUS IONS

A.P. KRUEGER, Univ. of California, School of Public Health, *Berkeley, California* 94720

The general research objective of this project is to assess the biological activities of gaseous ions. During the past 13 years we hve developed methods and facilities which make it feasible to expose bacteria, protozoa, higher plants, insects and small animals to predetermined concentrations of small air ions in controlled and monitored microenvironments. We have demonstrated a series of physiological changes in experimental subjects directly attributable to inhalation of these ions.

We wish to continue this work with particular attention to the effects of air ion depletion, unipolar ionized atmospheres and air containing various ratios of positive to negative air ions on: 1. the biogenic amines of the mouse brain. 2. the blood levels of serotonin in the mouse. 3. the nucleic acid metabolism of higher plants. 4. host-virus models including (a) the honey moth-Chile irridescent virus, (b) the mouse-influenza virus. 5. longevity of Drosophila melanogaster. 6. genetic phenomena in Drosophila melanogaster.

Items 1 and 2 will provide some insight into the relations between air ion imbalance associated with naturally occurring meteorological conditions and alterations in mood, affect and soma of exposed subjects. Items 3, 4 and 5 will extend our work to other areas of basic concern in which mechanisms of air ion action hopefully may be deciphered.

1.0171, TOBACCO SMOKE AND LUNG BIOCHEMISTRY
C.E. CROSS, Univ. of California, School of Medicine, *Davis, California* 95616

The lung, the principal organ for external gas exchange, is exposed to various effete inhalants including bacteria. Pulmonary alveolar macrophages (PAMs) constitute the major cellular host defense apparatus that protects the lung from these noxious inhalants. The interactions of tobacco smoke with the lung are reported to cause pathophysiologic manifestations, but little is known concerning the underlying biochemical mechanisms. The study will provide information concerning the effects of tobacco smoke lung cells. Using PAMs and other lung cells as models, cigarette smoke effects will be expressed in terms of biochemical malfunctions. These effects presumably underlie early events that are manifest by overt pulmonary pathological changes.

The rationale of our approaches is that (i) cigarette smoke may directly affect lung cells and interfere with their energy metabolism, leading to impairment of pulmonary gas exchange and pathological cellular changes; (ii) Respiratory disorders may occur from cigarette- induced impairment of PAM phagocytic functions; and (iii) cigarette smoke may interact with other noxious environmental inhalants so as to cause addative insults to lung cellular biochemical machinery.

The studies undertaken may lead to the establishment of precautionary and possible therapeutic measures relevant to a better definition of the biochemical hazards of cigarette smoke exposures.

SUPPORTED BY Amer. Med. Assn. Educ. & Res. Foundation

1.0172, EFFECTS OF CIGARETTE SMOKE ON THE PULMONARY LYMPHORETICULAR SYSTEM
C.E. CROSS, Univ. of California, School of Medicine, *Davis, California* 95616

The effects of cigarette smoke on the renewal rates of pulmonary alveolar macrophages will be studied utilizing the Es-2 marker enzyme system of inbred RF/Al mice. The effects of cigarette smoke on pulmonary macrophage cellular kinetics will be compared to the effects of a wide variety of other exogenous and endogenous agents such as air pollutants and corticosteroids.

SUPPORTED BY Council for Tobacco Res. - New York, N.Y.

1.0173, PULMONARY EFFECTS OF ENVIRONMENTAL OXIDANT POLLUTANTS
D.L. DUNGWORTH, Univ. of California, School of Veterinary Medicine, *Davis, California* 95616

Rats and non-human primates will be exposed to oxidant air pollutants of a photochemical type, primarily ozone and nitrogen dioxide, at concentrations approximating high ambient levels. Structural-functional correlates of the effects will be assessed by integrated physiologic, morphometric and biochemical studies. Specific pathogenetic relationships to be sought, by determination of appropriate parameters, are: 1) Between changes in pulmonary function and morphometry of airways, alveoli and the blood-air barrier. 2) Between decreased resistance to infection and enzymatic defects and lipid peroxidation in pulmonary alveolar macrophages. 3) Between morphometry of the blood-air pathway and lipid peroxidation.

Other hypotheses to be tested concern the concept of oxidant lung damage as an acceleration of lipid peroxidation-molecular damage and the possible prophylactic effect of diets with increased content of vitamin E and other antioxidants.

The integration of functional, morphologic and biochemical observations from exposures to realistic levels of pollutants will allow more confident predictions regarding possible long-term effects in man. Comparisons between rats and non-human primates will substantiate the validity of extrapolating from experimental animals to man. One outcome will be the establishment of rational tolerance limits for concentrations of oxidant pollutants in ambient air.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0174, EFFECT OF POLLUTANTS ON PULMONARY BACTERIAL DEFENSE
E. GOLDSTEIN, Univ. of California, School of Medicine, *Davis, California* 95616

The proposed studies are designed are to: 1) delineate the effect of atmospheric exposures of various concentrations of nitrogen dioxide on murine pulmonary anti-bacterial defense mechanisms; 2) evaluate the combined effect of ozone and nitrogen dioxide on murine defenses; and 3) develop a biological model which can be used to establish air quality control standards. Investigations performed during the first year of this grant demonstrated that short term exposures to relatively low levels of ozone O.62 ppm inhibited murine ability to kill inhaled bacteria (1, 2). We plan to investigate the effects of nitrogen dioxide and nitrogen dioxide in combination with ozone in a like manner using murine pulmonary bactericical activity as the test parameter. Mice will be exposed to combinations of the two pollutants using an isobologram type of experimental design. Pulmonary bactericidal activity will be measured by previously published aerosol techniques. Ozone and nitrogen dioxide will be monitored continuously using equipment which minimizes cross-interference. If ozone and nitrogen dioxide manifest an additive or synergistic result, we expect to observe an adverse effect of the combination at concentration levels which are less than those necessary to cause impairment by each agent alone and which in some instances will approximate atmospheric pollutant levels. The demonstration of murine bactericidal dysfunction at ambient oxidant levels could be used as an air quality control measurement.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0175, ANATOMY OF THE RESPIRATORY SYSTEM IN HEALTH AND DISEASE
W.S. TYLER, Univ. of California, Agricultural Experiment Sta., *Davis, California* 95616 (CA-V0-ANA-2150)

OBJECTIVE: Determination of structure and function of resporatory system in health and disease. Compare and correlate the structure and function of respiratory system in animals and man.

APPROACH: Application of as many methods as possible to lungs from a variety of animals will be made. Cardiac pulmonary function tests will be applied to a number of normal and diseased animals.

PROGRESS: Our comparative studies of chronic pulmonary emphysema have been summarized and brought to publication (87 below). Additional studies, using scanning electron microscopy in addition to transmission electron microscopy and histochemistry, are in progress. We hope to reveal the basic nature of pores in the interalveolar septum and their relationship to the various cell types. Several experiments designed to reveal the reaction of the respiratory system to known air pollutants, specifically ozone, have been conducted and the results are being analyzed. Some of the analyses will be deferred until the quantitative image analyzing computer, which has been funded, is received. Additional experiments will be conducted during 1970. We have continued our studies of the avian lung by applying scanning electron microscopy, transmission electron microscopy, and histochemistry to lungs from chickens and Japanese quail. We have developed new procedures to prepare pulmonary tissues for scanning electron microscopy and will present results of our studies at three scientific meetings this year. Our most important observations concern the nature of the atria, the epithelium of the atria, and the manner of communication between the tertiary bronchus, atria, and air capillaries.

1. AIR QUALITY

SUPPORTED BY California State Government - Sacramento

1.0176, CHEMICAL ELEMENTS OF BIOLOGICAL FLUIDS AND TISSUES
L.R. ANSPAUGH, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

Essential information is lacking on the normal occurrence and distribution in man of most of the elements, even though there have been many studies on those presently known to be essential or highly toxic. Variations with age, sex, health state, and dietary levels are virtually unknown as are the homeostatic control processes. As man is increasingly exposed to various less familiar elements, whether by fallout, industrial contamination, or other means, such information becomes essential if the hazards of exposure to stable or radioactive isotopes are to be intelligently evaluated and controlled.

The long-range objectives of this program are (1) to fill in these gaps of knowledge as far as possible within the limits of our presently established techniques of x-ray spectrography and optical emission spectroscopy, and (2) to pursue other methods to answer specific questions raised by this and other prediction programs. Basically our present methods are applicable to the study of 73 elements from atomic number 3 to 92. The unique contribution of this program is its ability to analyze for many elements, of which a great number have not been studied previously.

A secondary objective is to compile and organize the available published information on the concentration of all elements in the various human tissues, and to tabulate them using a single, consistent set of units.

Results: Advanced capabilities have been established in x-ray spectrography and optical emission spectroscopy. Studies on the elemental content of brain regions and livers are nearly complete. An interesting finding is that approximately 15 percent of the samples from mentally retarded individuals contain unusually high amounts of heavy metals indicating that the incidence of metallic poisoning may be considerably higher than anticipated.

SUPPORTED BY U.S. Atomic Energy Commission

1.0177, INTERACTION OF ELECTRON ACCEPTORS WITH CHLORPROMAZINE
H. KEYZER, Calif. State College, School of Letters, *Los Angeles, California* 90032

Recent studies in our laboratory have indicated that electron acceptors such as sulfur dioxide and nitrogen dioxide, major components of polluted air, interact with chlorpromazine to form a product which alters the effect of this drug in terms of hypothermia and sedation in white mice.

It is proposed to study in detail the exact nature of the above interaction product by resonance techniques, spectroscopic methods and electrochemical means.

It is further proposed to inject the interaction product (in which the molar concentration of the electron acceptor is varied from 0 to 10) into statistically significant populations of mice and to observe the effect of the modified drug on a comparative basis with the pure drug, pure acceptor and controls in terms of the physiological indicators, hypothermia and sedation.

The objectives of this study are: to discover what the precise nature is of the modification induced in chlorpromazine by the action with specific electron acceptors, whether CPZ activated by extraneous electron acceptors is consonant with the primary event of 'in vivo' activation of the drug; whether 'in vitro' activation can provide a new technique to understand the basic action of the drug.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0178, SMOG EYE IRRITATION - EXPERIMENTAL AND CLINICAL STUDIES
A.T. SAPSE, Univ. of California, School of Letters, *Los Angeles, California* 90024

The aim of this study is the assessment of harmful effects of air pollutants on the eye after short and long term exposure to smog, artificial smog and smog components. The principal components of the eye presumably exposed to the action of smog, i.e., tears, cornea conjunctival area and the lacrimal gland system will be examined.

The results of studies performed so far clearly indicate that the problem of smog eye irritation is not just a transient irritation of the eyes. Apparently significant changes are taking part as a result of long-term exposure.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0179, INHALATION OF WHOLE SMOKE, SYNTHETIC SMOG, & AMBIENT AIR ON THE RESPIRATORY TRACT & OTHER ORGANS OF PATHOGEN-FREE MICE (ABBREV)
C.G. LOOSLI, Univ. of Southern California, School of Medicine, *Los Angeles, California* 90033

Studies are being continued to determine the effect of synthetic smog on the lungs of pathogen free male and female mice. Synthetic smog consists of NO2 (0.4 to 0.8 ppm), 03 (0.2 to 0.4 ppm), SO2 (0.8 to 1.2 ppm), and CO (4.0 to 6.0 ppm). These are levels found in Los Angeles ambient air. It does not contain particulates. Control animals of similar age will be housed in filtered air rooms. Four groups of animals will be studied. Group one will be subjected to long term exposure to synthetic smog. Group two will be exposed to synthetic smog and cigarette smoke. Group three, living in filtered air, will be exposed daily to fresh cigarette smoke alone. Group four will serve as control and be housed in filtered room air. Periodically, mice from the four groups will be sacrificed and comparative studies of the lung changes in the four groups will be made. Sufficient animals will be used to make observations over a twenty-four months' period.

SUPPORTED BY Council for Tobacco Res. - New York, N.Y.

1.0180, RESPIRATORY TRACT AIR POLLUTANTS AND BIOLOGICAL AGENTS
C.G. LOOSLI, Univ. of Southern California, School of Medicine, *Los Angeles, California* 90033

Studies begun last year will be continued. They are concerned with the role of certain known air pollutants, nitrogen dioxide (NO2), sulfur dioxide (SO2), ozone (O3) and carbon monoxide (CO), airborne inorganic particulates, and biological agents (Staphylococcus aureus and influenza PR8-A virus), alone and in combination, on the health and particularly the lungs of pathogen free mice. Comparable control groups of mice of similar age and strain will be housed in filtered air rooms. Pathogen free mice will be exposed for 24 months to a 'synthetic smog' (SS) composed of NO2, SO2 and CO in amounts found in ambient Los Angeles air. Similar groups of mice will be housed in a filtered air room (FA). Sufficient animals will be exposed so that smaller groups of SS and FA exposed mice can be sacrificed for detailed study of the lungs by histological, histochemical, biochemical and electron microscopic procedures. Mice living in SS and FA will also be exposed to particulates collected from the Los Angeles atmosphere. Likewise, mice in SS and FA will be subjected to airborne influenza virus or Staphylococcus aureus to assess the role of these biological agents in producing changes in respiratory tract structure. The above studies are designed to evaluate the respective roles of gaseous, inorganic particulates, and biological agents in the production of lung lesions which might resemble chronic bronchitis or emphysema in man.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0181, ACUTE TOXICITY OF HEATED ASBESTOS
J. JAGATIC, U.S. Veterans Administration, Hospital, *Martinez, California* 94553

Purpose or significance of project (hypothesis): The desire of the Investigator is to establish firm evidence that 1) heated asbestos is acutely toxic for mice if it is injected intraperitoneally. 2) That mice fed with heated asbestos develop signs of acute toxicity. 3) Observation of mice exposed to breathing dust from heated asbestos. If these experimental observations are reproducible with accuracy and consistency comparison is obvi-

ous with the workers in the asbestos industry, steel mills, shipping yards, brake lining and many other occupations. Preventive measures should be introduced to help many veterans from becoming seriously ill.

Plan of approach (design): Experimental animals (mice) should be divided into 4 groups. Each group should be composed of 100, 2 month old white female mice from the same breed. 1) First group of 100 mice should be injected with 1cc emulsion of 50% heated asbestos in N/saline. 2) Second group should have mixed in the daily food heated asbestos in powdered form without being diluted and offered to the animal daily. 3) Dust chamber (closed box without ventilator) should be used 2 hours daily to expose the animal to dust. 4) Fourth group should be controlled animals applying on them the same technique as above but instead of heated asbestos, talcum powder as a media.

Technique: 1) Each animal will be autopsied and tissue examined by light and electron microscope. 2) Blood of these animals will be examined by micro method for the chemistry.

SUPPORTED BY U.S. Veterans Administration

1.0182, CARBON MONOXIDE AND HUMAN INFORMATION PROCESSING

R.R. BEARD, Stanford University, School of Medicine, *Palo Alto, California* 94305

The aim of the proposed research is to examine the effects of exposure to low concentrations of carbon monoxide (CO) on several levels of human performance within the context of information search, selection and manipulation. CO effects on information processing in both visual and auditory modalities will be evaluated. This will include tests which are an extension of ongoing research in our laboratory on vigilance, simple discriminatons (including temporal discrimination), as well as further work on memory and more complex tests of cognitive processes.

Multiple measures will be used to evaluate the effects of CO within this framework of information processing by human subjects. These measures will include behavioral responses, electrophysiological activity (EEG and evoked potentials), and eye movements, when each is applicable to the testing situation. The amount of CO present in the blood will be determined by estimating the carboxyhemoglobin (COHb) levels present during all testing using both blood samples and breath samples. Testing equipment and methodology developed in our behavioral toxicology laboratory over the past eight years will continue to have direct application and use in the current proposed studies. The reserch is directed toward the practical objective of understanding the extent of impairment of human performance (both psychological and physiological) from exposure to CO and thus aid in the establishing of air quality standards relevant to environmental conditions. The methods which are being developed are applicable to a wide variety of toxic agents, both industrial and pharmacological.

1.0183, BIOCHEMICAL EFFECTS OF AIR POLLUTANT OXIDANTS

J.B. MUDD, Univ. of California, School of Agriculture, *Riverside, California* 92502

It is proposed that studies of the reaction of ozone with reduced nicotinamide adenine dinucleotides be continued. The nicotinamide ring is cleaved but it remains to identify the products. The importance of this oxidation under physiological conditions is to be studied first by comparing its oxidation with that of glutathione, both compounds being exposed to ozone simultaneously.

Reaction of ozone with lipoprotein systems: Earlier studies with pure preparations of amino acids, proteins and fatty acids have now led to a study of ozone on more complex lipoprotein structures, in particular the membranous structures of cells. Ozone reacts both with unsaturated fatty acids and with certain amino acids. The question is whether the protein or the lipid of the lipoprotein system is first affected by ozone. We propose to measure the reaction of ozone a) with unsaturated fatty acids in the presence and absence of glutathione; b) with pure lecithin in the presence and absence of glutathione and c) finally with subcellular organelles in the presence and absence of glutathione. Glutathione is normally oxidized by ozone. The above studies use glutathione as a competitor with the unsaturated fatty acids. Oxidation of the unsaturated fatty acids will be measured both by assay of malonaldehyde and peroxide.

1.0187, BIOCHEMICAL AND HISTOCHEMICAL INVESTIGATIONS OF ENZYME SYSTEMS IN MAMMALIAN LUNG

A.E. VATTER, Univ. of Colorado, School of Medicine, *Denver, Colorado* 80220

In this project, we propose to locate precisely the site of enzyme- substrate reactions in the cells of pulmonary tissue by electron microscopic cytochemical methods. The findings will be correlated directly with biochemical studies of isolated systems or cell fractions containing similar enzymatic activities. The initial approach is to find synthetic substrates which will undergo an enzymatic reaction such that one of the products of hydrolysis forms an insoluble compound rendering the site of reaction electron-opaque. The substrate will be designed so that the product can also be determined spectro- photometrically. Once the reaction has been detected in a specific organelle of the cell, biochemical preparations will be made of these organelles and similar reactions followed using the same substrates. These subfractions will be examined by electron microscopy as a further control. Studies of the effects of inhibitors and thermal denaturation of these enzymes in whole tissues and after isolation, and to study the kinetics of the purified enzymes using a variety of substrates under various experimental conditions are planned. Enzyme preparations, tissue slices and animals will be treated with substances found in polluted air (noxious gases and irritants) to determine any effect upon such enzyme-substrate reactions.

SUPPORTED BY Amer. Med. Assn. Educ. & Res. Foundation

1.0188, PROPERTIES OF PARTICULATE POLLUTANTS

M.L. CORRIN, Colorado State University, School of Engineering, *Fort Collins, Colorado* 80521

Research is continuing on the extent of adsorption of gaseous pollutants such as sulfur dioxide on atmospheric particulates and simulants. Isotherms will be obtained at several temperatures for the adsorption of pure sulfur dioxide; surface areas of the solids will also be measured. Heats and entropies of adsorption will be calculated. Isotherms for the adsorption of sulfur dioxide from air at several temperatures and relative humidities will also be determined and the desorption rates at high temperatures and relative

humidities (lung conditions) will be measured. The concentrations of sulfur dioxide (and the corresponding pressures) will be in the range of 0.05 to 10 ppm. From this information a model for sulfur dioxide transport via the particulate adsorption and desorption route into the lung will be developed. The adsorption of pure sulfur dioxide will be measured with the aid of a sensitive pressure transducer and a volumetric adsorption system. The adsorption of sulfur dioxide from air will involve a volmetric system with determination of sulfur dioxide in small volumes of air with a microcoulometer.

1.0189, IMPACT ON MAN OF ENVIRONMENTAL CONTAMINATION CAUSED BY LEAD
H.W. EDWARDS, Colorado State University, School of Engineering, *Fort Collins, Colorado* 80521

The major purpose of this proposed research is to develop and test an interdisciplinary mechanism for studying environmental contamination problems using a system approach. The purpose of the system approach is to provide the kind of broadly based information concerning the movement of a contaminant through the environment which will be useful in evaluating the nature and extent of a possible environment hazard. Examples of such contaminants include heavy metals such as lead and mercury, combustion-produced carcinogens, pesticides, etc.

The selection of lead for the model system offers several advantages in that it occurs in demonstrable amounts in the environment, has known deleterious health effects, and can be traced in its movement by newly-developed isotope-ration measurement techniques. The proposal has been well developed and the scientific staff is qualified to conduct the proposed research. Arrangements have been made for interactions between Colorado State University and other institutions interested in similar problems.

1.0190, EFFECTS OF DENTAL AEROSOLS ON OPERATORY AND SUBMARINE ENVIRONMENTS
M.A. MAZZARELLA, U.S. Navy, Submarine Medical Center, *Groton, Connecticut* 06340

Technical Objective: Develop corrective methods for reduction or elimination of contamination hazards associated with airborne dissemination, transfer, or reentrainment of microorganisms and toxic products resulting from dental procedures and naso-oral manipulations in submarine, dental clinic, and underwater habitat environments.

SUPPORTED BY U.S. Dept. of Defense - Navy

1.0191, EFFECT OF EXPOSURE TO THE TOTAL SUBMARINE ATMOSPHERIC ENVIRONMENT ON PHYSIOLOGICAL FUNCTIONS
K.E. SCHAEFER, U.S. Navy, Submarine Medical Center, *Groton, Connecticut* 06340

Technical Objective: Determine physiological effects of atmospheric contaminants in submarines and to carry out controlled experiments on physiological effects of CO2, CO, ions and aerosols.

SUPPORTED BY U.S. Dept. of Defense - Navy

1.0192, ATMOSPHERIC POLLUTION AND RESPIRATORY DISEASE
R.E. SNELL, Hospital for Sick Children, *Washington, District of Columbia* 20017

The long term goal of studies carried out under this project is to describe the concentration - time relationships necessary to produce a change in respiratory function when an individual with pulmonary disease is exposed to specific agents associated with air pollution. In the initial years of support, the investigators were concerned with the systematic evaluation of various tests of function in children with asthma and in the design of an Environmental Control Unit where it would be possible to carefully control and monitor barometric pressure, temperature and humidity. Studies are currently being carried out in the unit to determine whether there is any improvement in function when the asthmatic child is removed from the usual urban environment to one that is pollution-free. By this approach, it is hoped to better define the sub-acute and chronic effects of exposure to various gaseous and particulate agents and to acquire data necessary to establish rational air quality standards.

1.0193, FURNISHING NOTICE OF RESEARCH PROJECTS RELATIVE TO ALL BIOLOGICAL INFORMATION
UNKNOWN, Smithsonian Institution, *Washington, District of Columbia* 20560 (EHSD-71-529)

The Contractor shall furnish all personnel, material and equipment necessary to perform the following: Furnish notice of research project relative to all biological information (exclusive of vegetation effects) concerning the following air pollutants: SOx, particulate oxidants, O3, NOx, Pan, CO, polynuclear organics, carcinogens, mutagen, teratogens, asbestos, aeroallergens, odors, H2S, HCl, Cl2, Pb, F, Cd, V, Mn, Zn, As, Ni, Cr, Cu, Ba, Se, Hg, B Be, auto exhaust, diesel exhaust, industrial emissions, or any additional material of future interest. On a quarterly basis, during the period from date of award through June 30, 1971.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0194, TOBACCO SMOKE CONTAMINATION IN AIR TRANSPORT AIRCRAFT
E.A. RICHARDSON, U.S. Dept. of Transportation, Federal Aviation Agency, *Washington, District of Columbia* 20590 (000573)

Frequent complaints have been received by the Federal Aviation Administration from airline passengers who alleged that cabin smoke levels are achieved on some flights which are harmful to health. An editorial in Science, December 22, 1967, has highlighted the adverse effects of air pollution by tobacco smoke. Some have contended that cabin tobacco smoke may compromise airmen flight performance.

Measurements will be made of the cabin environmental levels of tobacco smoke products during typical air transport flights. Carbon monoxide will be measured with a MSA CO indicator and chart recorder. Polycyclic benzopyrene type compounds will be determined with a battery operated pump and charcoal tubes. In addition, particulates will be obtained for analysis with a pump, charger and filter-paper device. Aldehydes, ketones, and aromatic hydrocarbons will be obtained by pump and charger, plus charcoal filter. Oxides of nitrogen and sulfur may also be determined. In a number of instances, passenger blood samples will be obtained just prior to the flight, during, and immediately after, so that carbon monoxide blood levels can be correlated with environmental levels. Also, smokers and nonsmokers will serve as subjects and a record will be maintained of the type of smoking done by each subject (cigarette, pipe, cigar) and how much, in order that a proper correlation and analysis can be made.

Coordination is effected with the U.S. Public Health Service in Cincinnati with respect to measurements, and with the U. S. Air Force regarding Military Air Transport flights during which cabin air samples are obtained.

Document provided by Highway Research Information Service.

1.0195, LUNG ALVEOLAR SURFACTANT - PHYSIOLOGICAL, BIOCHEMICAL, AND THERAPEUTIC ASPECTS IN CARDIOPULMONARY DISEASE
L.T. ELLISON, Medical Coll. of Georgia, School of Medicine, *Augusta, Georgia* 30902

The purpose of this project is (1) to determine the role of lung alveolar surfactant in a variety of cardiopulmonary diseases, (2) to establish the mechanism (s) of alteration, and (3) to correlate this information in the anticipation that it may be used to prevent or treat conditions in which surfactant is abnormal.

Surfactant will be determined in lung biopsies obtained in patients undergoing thoracotomy and in patients at postmortem, an attempt being made to obtain tissues from both normal and abnormal appearing areas. Data from the clinical record will be carefully recorded in order that it may be correlated with the surface tension measurements. Factors suspected of having some influence on surfactant will be especially noted.

The effect of various concentrations of oxygen and the effect of ozone and other air pollutants on surfactant will be studied in animals.

The alveolar bubble method will be used to evaluate surfactant.

SUPPORTED BY Georgia Heart Association

1.0196, ENVIRONMENTAL RADIOACTIVITY AND TRACE ELEMENTS IN MAN

R.B. HOLTZMAN, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-38)

The concentration of Ra 226, Pb 210, Po 210, stable lead and other stable trace elements in food, water, air, and excreta are being correlated with the concentrations of these same elements in human tissue. Material has been obtained from three geographic areas for which human exposure to lead and Pb 210 differs markedly. Materials from the Eskimos and Indians in Canada and from Puerto Rico show a high and low rate of exposure to Pb 210, Po 210 and Pb, respectively. In addition, a complete metabolic balance study for Pb 210, Po 210 and Pb in man has been initiated with Herta Spencer at Hines Hospital. From these and other studies studies, the relative contribution of food and air to the lead content of man under normal environmental conditions of exposure can be derived. Similar relationships can be derived for other trace elements from these same materials.

SUPPORTED BY U.S. Atomic Energy Commission

1.0197, AIR POLLUTION MEDICAL RESEARCH CONFERENCE

F.W. BARTON, Amer. Medical Association, *Chicago, Illinois* 60610

The objectives of the American Association in conducting this project are: (a) to encourage scientific investigation of the effects of air pollution on health; (b) to critically examine the present status, needs and goals in air pollution measurements in order to achieve better correlation of physical, chemical and biomedical data; (c) to present original research findings and to explore application of these findings to air pollution control efforts and to medical care.

It is felt that the scientific results of research are not reaching the medical profession and other interested persons who are most involved in the use of those results in a form they could best understand and take appropriate action. There is a little too much of the 'researcher speaking to other researchers.' While this in itself is valuable, it is believed that the program should try to answer questions by interested physicians and others as to what they should do about what research shows to be true.

To more effectively implement the goals of this project, therefore, the Conferences will be organized around specific problems which not only enable the speakers to present their current research, but will effectively reach physicians, the allied professions and even the general public. To aid in this attempt to reach and activate an audience which can implement action in this field, Summary sessions will attempt to tie together all the presentations in a manner most conducive to practical use. The AMA expects that not only will the program be sophisticated, but that the long-range accomplishments will be great.

1.0198, STUDIES OF ENVIRONMENTAL AIR POLLUTANTS

G.T. OKITA, Northwestern University, School of Medicine, *Chicago, Illinois* 60611

The objective of the proposed investigation is to obtain information on the biological and biochemical effects of environmental air pollutants on experimental laboratory animals. More specifically, we are interested in investigating the following two problems: 1) The locus of action of aromatic polycyclic hydrocarbons and 2) in vivo metabolic effects of environmental noxious gases.

For studies concerned with the site of action of polycyclic aromatic hydrocarbons (PAH), we are interested in determining the molecular nature of the carcinogenic action of PAH. Nonplanar endosuccinate derivatives of dimethylbenzanthracene and dibenzanthracene are being synthesized and tested for their carcinogenic activity. Preliminary findings indicate that both derivatives are carcinogenic in mice and rats. Radioactive derivatives are also being prepared for drug metabolism studies to determine whether they are broken down to parent compounds. If these non-planar compounds are confirmed to be carcinogenic and are not broken down to PAH, these findings may invalidate the current hypothesis that PAH acts by intercalating between base pairs of DNA.

For studies concerned with investigating in vivo metabolic effects of environmental noxious gases, we are interested in determining the type of biochemical lesion induced by SO2. In vivo biochemical studies are being conducted to compare differences in oxidation of select C14- labeled biochemical intermediates between control animals and animals exposed to SO2. Both acute and chronic exposure to varying concentrations (0.1 to 20 PPM) of SO2 will be tested. Histologic examination of pulmonary tissue will also be performed to determine whether biochemical changes can be detected before pathological changes. Similar studies also are planned for NO and NO2.

1.0199, THE EFFECT OF INFLUENZA VIRUS AND NICOTINE ON THE NUCLEAR STRUCTURE OF CILIATED HUMAN EPITHELIUM

J.J. BALLENGER, Evanston Hospital, *Evanston, Illinois* 60201

The general objective of the project here proposed is to investigate the effects of various air pollutants upon the structure and function of the muco-ciliary cleansing system of the respiratory tract of man and also of possible nuclear changes in the cells so exposed. The rotating explant method will be used in the investigations since it provides an isolated epithelial (ciliated) 'organ' which performs work and which can be subjected to quantitative experimentations and analysis. A lower animal model will be actively sought in order to make the method more flexible. It is also our aim to determine whether or not there is a possible relationship of air pollutants and/or viruses working separately or in concert to the appearance and progression of respiratory malignancy.

Other avenues of study include: further elucidation of the action of substance such as nicotinamide-adeno-dinucleotide upon muco-ciliary function, effect upon ciliary activity of the induced allergic states, the effect upon this system of corticosteroids and other hormonal substances.

We will also, as time permits, observe the effects of certain crude phenols and tobacco tars on the muco-ciliary cleansing system.

Finally, if the epithelial cells survive and grow they will be examined every five to seven days for nuclear pattern shifts. Time-lapse photography will be used to record growth changes where feasible.

SUPPORTED BY Amer. Med. Assn. Educ. & Res. Foundation

1.0200, STRUCTURE AND FUNCTION IN TRANSPORTING EPITHELIA

J.L. OSCHMAN, Northwestern University, School of Arts, *Evanston, Illinois* 60201

Recently much has been learned about the biophysical basis of membrane transport. One of the most significant contributions is the standing gradient hypothesis, which can account for the structural and functional characteristics of fluid transport by both absorptive and secretory epithelia. Our work concerns the validi-

ty and implications of this important hypothesis. The main emphasis is on the structure and function of specializations of the cell surface, such as microvilli, basement membrane intercellular spaces, basal infolds, and canaliculi. The epithelia chosen for study have particular advantages for study of transport mechanisms, and for considering the general mechanisms of absorption and excretion in animals. The latter aspect of the study has relevance to the problem of the effects of environmental pollution on biological systems.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0201, NEUTRON ACTIVATION OF BIOLOGIC SPECIMENS
Y.T. OESTER, U.S. Veterans Administration, Hospital, *Hines, Illinois* 60141

Progress: Emission spectroscopy (spark), neutron activation, and atomic absorption techniques continue to be employed in the studies of urine, serum, finger nails, aortic and myocardium. Collaborative study with the World Health Organization (WHO) has been implemented on the possible role of trace elements in cardiovascular function. This collaborative venture was extended to Argonne National Laboratory (reactor facilities) and to Loyola University Chemistry Department (emission spectroscopy facility). Specimens continue to be collected and are being received from different regions of the world (New Zealand, Jamaica, etc.). During this period of time a second major study was initiated. This study is on a possible relationship of trace elements normally found in the atmosphebe of metropolitan Chicago area to elements observed in inhabitants with normal lungs and lungs with various functional disorders. In addition to lungs, the following organs are also collected: spleen, liver and mediostinal lymph nodes. These organs may be used in future studies.

SUPPORTED BY U.S. Veterans Administration

1.0202, O3 & NO2 TOXICITY IN NORMAL & ANTIOXIDANT-FED ANIMALS
A.S. CSALLANY, Univ. of Illinois, School of Agriculture, *Urbana, Illinois* 61801

Experiments will be conducted to determine the chronic effects of small concentrations of the pollutant gases NO2 and O3 on the metabolism of rats and mice. Animals will be exposed continuously throughout their life span to one of the following concentrations of these gases: 0.05 ppm NO2 , 0.15 ppm NO2, 0.15 ppm O3, 0.45 ppm O3. The following parameters of response will be determined: (a) gross and histopathology of tissues and organs (b) growth rate (c) reproductive performance (d) longevity (e) concentrated of lipofuscin pigments in the tissues (f) levels of conjugated dienes in the tissue lipids (g) amounts of carbonyl compounds associated with tissue lipids (h) rate of oxidation of vitamin E in vivo (i) peroxidase activity in the tissues. The effect on the susceptibility of the animals to these oxidants of depriving them of the natural lipid antioxidant vitamin E, of providing them with high levels of this vitamin and of administering the synthetic antioxidant DPPD, also will be determined.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0203, EXPERIMENTAL INFECTIVE PNEUMOCONIOSIS
S.H. ZAIDI, Industrial Toxicology Res. Ct., *Lucknow, Uttar Pradesh, India*

The objective of the study is to determine the role of infection and immune reactions in the development of asbestosis and other dust related pneumoconioses.

In the pathogenesis of dust related pneumoconiosis one widely held view has been that the dust itself acting alone and unaided in the lung tissue is the initiating agent of the disorder e.g., silicosis. In other dust related pneumoconioses, such as asbestosis, byssinosis, talcosis, and coal miners pneumoconiosis, the possible role of infective organisms is not clear except in pulmonary massive fibrosis among coal miners. That an infection can exaggerate or modify the form of dust induced pneumoconiosis requires further investigation and documentation. It may be the case that there are two processes involved in dust pneumoconiosis working together which augment the effects of each separately - the dust and the infective agent.

A study will be made of the combined action of the different dusts which are common contaminants of the air in asbestos and coal mining and processing and the various strains of suspected pathogens present in the mines, processing plants and lungs of the exposed workers. The respirable dust will be collected from various coal and asbestos mines and processing plants. The organisms will be isolated from the respiratory tract of mine and processing plant workers.

1.0208, A PROGRAM IN ENVIRONMENTAL PHYSIOLOGY AND TOXICOLOGY
R.L. RILEY, Johns Hopkins University, School of Public Health, *Baltimore, Maryland* 21205

The major objective of this program is to pursue a variety of investigations related to the maintenance of human health in the face of environmental hazards. We shall approach this objective

by elucidating mechanisms of action on body tissues and will concentrate on studies in the following areas where members of the department have greatest competence: A) Responses of the respiratory system to airborne agents; B) Physiological and behavioral evaluation of carbon monoxide hazards; C) Toxic effects of trace metals; D) Synergistic and antagonistic mechanisms responsible for changes in toxicity of environmental agents; and E) Cooperative prospective study of a human population with reference to the incidence of cerebral vascular disease. Because of the wide variety of disciplines required, we shall cooperate with other departments and where possible coordinate activities in order to bring the full potential of the School of Hygiene and the entire University to bear upon problems of the environment.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0209, ENVIRONMENTAL FACTORS AND CHRONIC BRONCHITIS
H.D. KERR, Univ. of Maryland, School of Medicine, *Baltimore, Maryland* 21201

The research objectives are to identify the relationships between respiratory health and environment. Interrelated investigation of human response by variation and patterns of respiratory function will describe in part the relationshps between specific significant environmental factors and agents as causing and/or influencing th course of chronic obstructive respiratory disease.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0210, FUNCTIONAL ADAPTATIONS TO ATMOSPHERIC CONTAMINANTS
W.H. TEICHNER, Amer. Inst. for Res. Behv. Sc., *Silver Spring, Maryland* 20910

This research is concerned with two problems: (1) The development of methods for evaluating the functional effects of air contaminating agents, and (2) the study of functional adaptations to such agents with a particular interest in adaptations to low level, long-term exposures. The approach is through both behavioral and physiological dependent measures. Containants to be studied will be nitrogen dioxide, formaldyhyde, and carbon monoxide.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0211, USSR LITERATURE ON AIR POLLUTION AND RELATED DISEASES
M.Y. NUTTONSON, Amer. Inst. of Crop Ecology, *Silver Spring, Maryland* 20910

The research goals for the coming year is to proceed with the survey, selection, and translation of USSR's technical air pollution literature as it relates: (a) to the nature of air pollution in the different industrial regions of the country, (b) to the effect of the specific physical environments of the various industrial regions of the Soviet Union on the propagation and dispersal of air pollutants as well as on the level of air pollution (c) to the biological effects of air pollutants, and (d) to methods of control of air pollution.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0212, AUTOMOBILE EXHAUST AND CHRONIC RESPIRATORY DISEASE
F.E. SPEIZER, Boston Dept. of Hlth. & Hosps., *Boston, Massachusetts* 02118

Epidemiological investigations into the factors relating to the occurrence and development of chronic non-specific respiratory diseases have, in general, followed a pattern of retrospective point prevalence studies. Increased levels of cigarette smoking and air pollution have been associated with the increased prevalence of chronic respiratory disease. Few prospective studies on the early stages of these diseases have been conducted. Until factors relating to susceptibility to chronic respiratory diseases are understood, it is unlikely that the increasing morbidity and mortality from these diseases can be controlled. To try to relate factors associated with these diseases to the development of disease, this study is designed to follow a selected segment of the population over an extended period of time and to record the rate of change of signs and symptoms associated with the development of chronic respiratory disease. Intense exposure to automobile exhaust and cigarette smoking are the major environmental agents to be evaluated. The assessment of the population will include interview by standard questionnaires, measurements of ventilatory capacity, evaluation of sputum production, both qualitatively from a bacteriological standpoint and quantitatively in amount, and an evaluation of the host response mechanisms by relatively detailed immunological analyses. Exposure to the environment will be assessed by several techniques. These will include environmental sampling as measured by standard monitoring equipment and personal sampling devices. In addition, measures of biologically incorporated constituents of automobile exhaust, particularly carbon monoxide and lead, will be determined. By studying prospectively a relatively healthy segment of the population, it is believed that factors related to susceptibility to chronic respiratory diseases in high risk individuals can be identified.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0213, PHYSIOLOGICAL RESPONSE TO ATMOSPHERIC POLLUTANTS
M.O. AMDUR, Harvard University, School of Public Health, *Boston, Massachusetts* 02115

The changes in the mechanical behavior of the longs of unanesthetized guinea pigs are used to assess the response to respiratory irritants. Emphasis continues to be on the effect of inert aerosols on the degree of response to irritant gases, with special attention to sulfur dioxide. The problem of the potency of irritant aerosols of different particle sizes will also remain an area of consideration.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0214, RESPIRATORY DISEASE AND ENVIRONMENTAL EXPOSURES
B.G. FERRIS, Harvard University, School of Public Health, *Boston, Massachusetts* 02115

Studies of various population groups are being made to determine whether specific airborne materials are factors in the causation of chronic respiratory disease. The ultimate purpose is to try to determine what constitutes safe or reasonably safe levels for exposure of populations. Populations studied to date have included samples of general populations - adults and children, asbestos workers, welders, and men exposed to toluene diisocyanate. Studies of the children involved absences from school and simple tests of pulmonary function. School absences even when corrected for non-sickness absences or examining only those due to respiratory illness did not seem to be adequately sensitive to demonstrate any effect of air pollution. Tests of pulmonary function, however, did indicate that the children in the more polluted area had poorer pulmonary function. Studies of the asbestos workers, welders, and pipe fitters showed impairment of diffusing capacity in the asbestos workers and more shortness of breath than in the other two categories. Analysis of these data is continuing. A repeat survey of a sample of the population from Berlin, N.H. has been made and is in the process of being analyzed. Preliminary results indicate that the levels of air pollution have not changed significantly since 1961 but the prevalence of respiratory disease when standardized for age, sex, and cigarette smoking has decreased slightly.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0215, FACTORS AFFECTING EXCRETION OF INDUSTRIAL POISONS
H.B. ELKINS, State Dept. of Labor & Indust., *Boston, Massachusetts* 02202

Fluoride Excretion in Workers Exposed to Freon - The relationship between urinary fluoride excretion and trichlorotrifluoroetane exposure will be studied in workers exposed to this solvent (perhaps other freons also) by urinalyses and air tests.

1. AIR QUALITY

Mercury Loss in Aged Urine - A study will be made to determine the effect of storage on mercury content of urine. Mercury loss through volatilization by bacteria found in aged urine has been reported. The practical significance of this finding will be investigated in urine samples from workers exposed to this element.

Relationship Between Urinary delta Aminolevulinic Acid and Lead Excretion - We will continue to perform lead and delta aminolevulinic acid analyses in urine from lead exposed workers to determine any useful correlation.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0216, AEROBIOLOGY PROGRAM

W.S. BENNINGHOFF, Univ. of Michigan, Graduate School, *Ann Arbor, Michigan* 48104

This integrated research program of the International Biological Program is designed to meet problems of airborne diseases, allergenic substances and biologically harmful pollutants of the air. It will organize, integrate, and extend present investigations of airborne spores, pollen, microbes, insects and other small organisms, and biologically significant nonliving materials such as toxic gases. It will identify critical problems not yet under investigation and will initiate new projects to meet those needs. The program will include segments for research technology, phytopathology, allergenic particles, transport of genetic materials, human and animal disease microbes, wind carried insects and other small animals, and gases toxic to organisms. The aerobiology programs will share efforts with several other IBP programs as well as various federal agencies, scientific societies, and private university laboratories. It is designed to increase the quantity and improve the quality of research on atmospheric dispersal of biologically significant materials, by emphasizing coordination of on- going activities in divergent areas.

SUPPORTED BY U.S. National Science Foundation

1.0217, TRACE AMOUNT SUBSTANCES IN ENVIRONMENTAL HEALTH

C.J. MARIENFELD, Univ. of Missouri, School of Medicine, *Columbia, Missouri* 65201

The sixth year of the study. The computer generated birth defect maps are being correlated with descriptive geographic maps characterizing the State of Missouri. It is apparent that geographic differences of statistical significance are present in both human and swine birth defects. In-depth studies of the high and low rate areas are being designed and several 'epidemics' of birth defects in swine have been investigated and reported. A geochemical census of the state is being conducted by the National Geologic Survey in collaboration with the University of Missouri Environmental Surveillance Center.

1.0218, TOXIC EFFECTS OF AIR FORCE CHEMICALS AND MATERIALS

L.E. LOVELESS, Lab. for Exptl. Biology., *Saint Louis, Missouri* (F33615-68-C-1492)

Technical Objective: Air Force operations involve the handling and use of chemicals and materials that can produce adverse effects. Toxic effects are established by exposing experimental animals to known concentrations of toxic chemicals and materials and determining what effects occur. Many effects occur internally and require the examination of tissue from the experimental animals. This data can then be used to estimate the effect on Air Force personnel.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0219, AIR LEAD POLLUTION - EFFECT ON THE G6PD DEFICIENT NEGRO

M.S. MCINTIRE, Univ. of Nebraska, School of Medicine, *Omaha, Nebraska* 68105

The purpose of this study is to demonstrate by several methods, increased hemolysis of the glucose-6-phosphate dehydrogenase deficient erythrocyte of negroes in the presence of increased blood lead due to air pollution. A survey will be made for G-6-PD deficiency and hematocrit in a negro population, in an area of high and of low air lead. Subjects with low G-6-PD activity by micro methemoglobin reductase screening will be investigated for blood lead, serum iron, G- 6-PD activity as measured by TPN reduction, and reticulocytes. Supplemental studies of auto hemolysis, potassium loss from rbc, ATP stability, and glutathione reductase activity will be carried out in samples of G-6-PD deficient negroes with 'high' and 'low' blood lead. It is postulated that lead affects sulfhydryl stability in the hexose monophosphate shunt as well as in the rbc membrane and that this would be more evident in a system characterized by an already decreased generation of TPNH, one of the two phosphophyridine systems concerned with maintenance of glutathione and other cellular thiols in their reduced state. Such evidence would be an original demonstration of an environmental hazard affecting, at the cellular level, approximately 13 percent of the negro population as well as a significant number of other persons with genetically determined deficiencies in red cell enzymes.

1.0220, EFFECTS OF CARBON MONOXIDE INDUCED ARRHYTHMIAS

D.E. HUTCHEON, New Jersey Coll. Med. & Dent., School of Medicine, *Jersey City, New Jersey* 07304

Experiments have been designed to study the influence of carbon monoxide inhalation on the vulnerability of the ventricles to catecholamine-induced arrhythmias. The effects of carbon monoxide exposure on the incidence and severity of ventricular arrhythmias produced by epinephrine and petroleum ether will be determined in dogs under pentobarbital anesthesia. The relationship of the electrocardiographic changes induced by epinephrine and petroleum ether to carboxyhemo-globin levels and oxygen saturation of the arterial blood will be investigated in animals exposed to carbon monoxide and in controls exposed to low oxygen concentrations in the inspired air.

SUPPORTED BY Bergen County Heart Assn. - New Jersey

1.0221, ETIOLOGIC SYNERGISMS IN DISEASES OF THE LUNG

R.L. SOPHER, U.S. Veterans Administration, Hospital, *Albuquerque, New Mexico* 87108

Most studies have been purely qualitative or crudely quantitative. Studies of a quantitative nature will be absolutely required if the earliest induced alterations in tissues are to be detected and differentiated from 'normal' aging effects. It is our aim to develop some quantitative data so that the very earliest changes in pulmonary structure after exposure to atmospheric contaminants may be found. At the same time, classic means of study such as light and electron microscopy as well as histochemistry will be used to determine the origin of those quantitative changes and, perhaps, to determine where the problem may be best attached to prevent the occurrence of such changes. The changes to be measured will include lung volume, alveolar volume, tissue volume, alveolar surface area, capillary surface area and volume, blood-gas barrier thickness expressed as arithmetic mean and expressed as harmonic mean.

Specifically, we hope to be able to differentiate pulmonary structural changes associated with air contamination from those occurring with aging at a level where conventional means of study would be fruitless. In this way the earliest morphological manifestations of air pollution may be determined. By applying other means of morphologic study such as histochemistry we shall try to determine the cause of differences in morphometric data. At a later stage in our program, we wish to study the combined effects of air pollution and pulmonary resistance to infection and mechanisms of such pulmonary resistance can be studied. Basic mechanisms of pulmonary injury and repair may be quantified and a better understanding of them acquired. This project has had significant re-direction since it was taken over by Dr. Sopher. We are now mainly inderested in quantitating the morphologic changes which occur in pulmonary anatomy in the lungs of animals normally aging, as a control group, and comparing these to a similar group of animals exposed chronically to low levels of pulmonary irritants. In this way we hope to determine if common

atmospheric contaminants play a significant part in the development of acceleration of chronic pulmonary disease. At this time we have decided to use the Mongolian Gerbil as an experimental animal since it has been shown to spontaneously develop emphysema and chronic bronchitis in old age. Gerbils have been acquired and are being bred so as to develop a usable colony.

SUPPORTED BY U.S. Veterans Administration

1.0222, PULMONARY REACTIONS TO GASEOUS ENVIRONMENTS
M. WITTNER, Yeshiva University, School of Medicine, *Bronx, New York* 10461

This research compares the pulmonary alterations resulting from exposure to irritant gas systems (O2, O3, NO2, SO2) with reference to alterations in structure and function of the gas-blood barrier at the ultrastructural level. Emphasis is on chronic exposures at low concentrations and on mechanisms underlying development and maintenance of tolerance and cross-tolerance to the toxic effects of these gases. Pathology will be interpreted in terms of structural and functional defects using electron microscopic cytochemistry and autoradiography. In addition, a cell model system will be studied in order to assess gaseous environments on macormolecular synthesis.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0223, A MODEL OF MUCOCILIARY FUNCTION AND VISCOELASTICITY
M.J. DULFANO, U.S. Veterans Administration, Hospita *Brooklyn, New York* 11209

The development of an experimental model in a. imals to study tracheal mucous clearance through the analysis of the relative contributions made by such participant variables as mucous viscosity, elasticity, depth of the mucous blanket and ciliary function, both under physiological conditions and after challenge by air pollutants.

SUPPORTED BY U.S. Dept of Hlth. Ed. & Wel. - P.H.S.

1.0224, URBAN CHRONIC DISEASE EPIDEMIOLOGICAL STUDY PROGRAM
W. WINKELSTEIN, State University of New York, School of Medicine, *Buffalo, New York* 14214

The objectives are to study 1) the relationships of social, environmental, and personal factors to blood pressure variability; 2) the relationships of environmental factors to the occurrence of chronic respiratory disease; and 3) coronary artery disease, particularly in women, and arteriosclerosis, including cerebrovascular disease. The personal and social data derived from the Erie County Air Pollution- Respiratory Function Study will be utilized to explore possible associations between pulmonary function and respiratory symptoms and such independnet variables as exercise, residence, ethnic background, and socio-economic status as well as to test specific hypotheses related to smoking, air pollution, and occupation. Collaboration with other groups will continue in order to utilize methodologies and competence unavailable within the Division. Continued emphasis will be directed toward studying the familial aggregation of conditions of interest and increasing concern will be placed on social and psychological factors. Retrospective studies of patients with particular conditions and appropriate controls will be utilized to explore selected hypotheses. Samples will be interviewed in the field; however, facilities are available for clinical examinations of selected individuals or appropriate population samples.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0225, EVALUATION OF CARCINOGENIC AGENTS IN CIGARETTE SMOKE
UNKNOWN, Amer. Health Foundation, *New York, New York* 10028 (NIH-70-2087)

The Contractor will exert its best efforts to perform research concerned with tobacco smoking and health.

Define the relative tumorigenic activity of tobacco smoke condensates obtained from tobaccos of the same grade and origin, but differing in contents of nicotine and smoke condensate yield. As a particular varient of the experiment, a cigarette made entirely of cellulose fiber will also be tested.

Define the relative tumorigenic activity of smoke condensate from cigarettes made of reconstituted tobacco sheets.

Develop more sensitive bioassay methods for a better understanding of the carcinogenic potential of cigarette smoke.

Cigarettes and tars will be subjected to physical and chemical analysis as follows: a. Physical parameters of cigarettes: Weight (g), Length (mm), Circumference (mm), Porosity (cms H2O), Pressure drop (cms H2O). b. Smoking data; Number of puffs, Rate of burn (mm/min.). c. Smoke delivery (mg/cig.): Smoke solids, Water, Dry smoke solids, Nicotine, Dry nicotine-free smoke. d. Smoke chemical data: Hentriacontane and total paraffin content, Nicotine and other alkaloids, Acetaldehyde, Acrolein, Formic acid, Phenol, HCN, Pyrene, Benz(a)Anthracene, Benzo(a)pyrene, Other analyses as indicated.

Perform epidemiological studies in man with the aim of identifying means of disease prevention. These studies will attempt to formulate answers to the following questions. a. Is there a dose relationship between risk of disease and extent of smoking habits? b. Is the risk of disease affected by different smoking habits such as inhalation, partial inhalation, etc? c. Is the risk of disease correlated with particular characteristics of the product smoke? d. Is the risk of disease dependent on the individuals susceptibility as a smoker? e. Is the risk of disease dependent on specific environmental factors?

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0226, ASBESTOS EXPOSURE-RISK IN DEFINED HUMAN POPULATIONS
I.J. SELIKOFF, City University of New York, School of Medicine, *New York, New York* 10029

This cluster of studies is designed to provide information concerning the community risk of asbestos-related disease by investigation of several defined human populations with related but different exposures. We have already defined the risk of direct occupational exposure in one industrially-exposed group; we are now obtaining data on the experiences of other populations associated with but distinguished from the defined group. Their asbestos exposures will have been derived from: 1. Indirect occupational exposure 2. Intimate personal environmental exposure 3. Neighborhood environmental exposure of general community group.

These studies are also intended to provide data with regard to three important variables not easily defined in studies among group with direct occupational exposure: effect of interrupted exposure, effect of age at onset of exposure and effect of minimal exposure.

The information derived from these studies is being correlated with other data currently being obtained concerning asbestos exposure in the general population (age, residence, occupation and disease being taken into account), to assist in the estimation of the overall risk resulting from asbestos exposure.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0227, AIR POLLUTION AND EMERGENCY ROOM VISITS
R.M. ALBRECHT, Columbia University, School of Public Health, *New York, New York* 10032

The purpose of this study is to examine the usefulness of statistics of visits to emergency rooms in two hospitals in New York City over the course of one year in surveillance of health effects of air pollution. Data to be analyzed consist of statistics of visits to emergency rooms for selected causes, and hourly measurements of pollutants and selected weather variables reported by the aerometric network of the New York City Department of Air Resources.

By use of the appropriate multivariate statistical techniques, the investigator expects to answer three questions: 1. Holding weather constant, is there a relationship between air pollution and

emergency room visits by cause? 2. Holding air pollution constant, is there a relationship between weather and emergency room usage by cause? 3. What combination of pollution and weather variables yield the best predictors of emergency room usage by cause?

SUPPORTED BY U.S Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0228, RED CELL DEFENSE MECHANISMS AGAINST AIR POLLUTION
R. BENESCH, Columbia University, School of Medicine, *New York, New York* 10032

The main purpose of this project is to ascertain to what extent a recently discovered mechanism, whereby certain organic phosphates of the red cell control and promote oxygen release to the tissues, might operate as a compensatory factor in protecting against the respiratory handicap associated with air pollution. Research will be concentrated in the first place on carbon monoxide intoxication, not only because it is a major air pollutant, but also because much previous work on its interaction with hemoglobin and erythrocytes provides a solid basis for studies of the kind described in this project.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0229, COLLECTION OF AEROMETRIC, METEOROLOGIC, BIOMETRIC OR OTHER HEALTH INFORMATION IN NEW YORK CITY, NEW YORK
UNKNOWN, New York City Hlth. Res. Coun., *New York, New York*

Air pollution measurements and information on specific health parameters must be collected in the cities included in the HESN by people located in the area. Collection sites are determined by NAPCA staff and instruments are checked and calibrated routinely but periodic collection according to a prescribed regimen are made under contract. Information relative to selected health parameters are likewise collected by contractors with regular review of activities by the project officer.

1.0230, PULMONARY DEPOSITION AND CLEARANCE OF DUST IN MAN
R.E. ALBERT, New York University, School of Medicine, *New York, New York* 10016

The overall purpose of this study is to characterize deposition and clearance in the respiratory tract of healthy humans and donkeys, and to determine the effects of various types of lung disease and impairment on these processes. Experiments are being carried out to extend the characterization of the physical and physiological parameters which control deposition in man for both nose and mouth breathing, especially the particle parameters: size, shape and electrical charge; and the respiratory variables: respiratory flow, tidal volume, state of chest expansion. The dynamics of normal and bronchial clearance are being investigated in both humans and donkeys. In the human studies the major effort is directed toward the characterization of normal bronchial clearance, the departures from normal resulting from exposure to cigarette smoke, and urban and occupational air contamination, and the deviations from normal characteristic of various lung diseases. Additional insight into the nature of the abnormalities will be obtained by comparing the clearance abnormalities observed in man with those which can be produced in donkeys following the inhalation of cigarette smoke and irritant gases.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0231, EFFECT OF AIR POLLUTION ON OBSTRUCTIVE LUNG DISEASE
E.H. BERGOFSKY, New York University, School of Medicine, *New York, New York* 10016

This project is designed to determine the effect of air pollution on lung function in patients with chronic and subacute obstructive lung diseases, such as chronic bronchitis and emphysema, by selectively removing the various airborn constituents, viz., particles, gases, and carbon monoxide in different experimental combinations, while relating the levels of these pollutants to studies of airway resistance, lung volume, blood gases and other parameters of lung function. When compared with previous studies, the present project will have the advantage of 1) selective removal of each pollutant or pollutant group from the ambience of a specially constructed environmental room, 2) the use of more precise measurements of lung function which may be made several times daily and require little disturbing intervention with the patient, and 3) maintenance of patients for periods up to one month in an area where levels of air pollution are constantly monitored.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0232, RESEARCH IN THE ENVIRONMENTAL HEALTH SCIENCES
N. NELSON, New York University, School of Medicine, *New York, New York* 10016

This grant provides core support for a broad program in the Environmental Health Sciences. The research under way and proposed is broadly relevant to adverse health effects from Environmental factors. The general objectives of the research are to define the nature and extent of such effects with the aim of instituting appropriate preventive or control procedures where required. Interests range from acute to chronic health effects including, in the latter, cancer and the degenerative diseases.

The research encompasses laboratory studies on the biochemical mode of action of environmental toxicants, exploratory studies aimed at improving the reliability and efficiency of predictive toxicological tests, improvement of diagnostic procedures for diseases possibly related to environmental factors, epidemiological investigations and field studies on the distribution of pollutants.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0233, MODE OF ACTION OF ALKYLATING CARCINOGENS
B.L. VANDUUREN, New York University, School of Medicine, *New York, New York* 10016

The purpose of the proposed research is to study the mechanism of action of alkylating carcinogens such as epoxides, beta-lactones and their nitrogen analogs and of aromatic hydrocarbon carcinogens. Studies will be aimed at the elucidation of the mode of action of aromatic hydrocarbon carcinogens by the synthesis and biochemical studies of possible proximal carcinogens of these agents. The aromatic compounds of interest are hydroperoxides, peroxides and epoxides. Metabolic studies will be carried out to determine whether these possible proximal carcinogens occur as metabolites on mouse skin. The 'in vivo' interaction of alkylating carcinogens with nucleic acids and proteins will be explored. 'In vitro' studies will be concerned with purines, protein precursors and other relevant model compounds.

Both of these groups of compounds occur widely as environmental contaminants and some of them are possible occupational hazards. Studies on the structure-activity relationships and mode of action of these agents are, therefore, relevant to cancer induction in man.

SUPPORTED BY Amer. Cancer Society Inc. - New York, N.Y.

1.0234, CHRONIC LUNG DISEASE RESPONSE TO POLLUTION FREE AIR
S.M. AYRES, Saint Vincents Hosp. Med. Ctr., *New York, New York* 10011

Over an eighteen month period residency in a controlled environment has been studied as to its effects on pulmonary function in patients with chronic airway obstructive disease. Outside air entering the unit is passed through high efficiency particulate and activated charcoal filters. This pre-filtered air is then refiltered in a unit directly over the beds of the patients. The particle counts from this over the bed filter is 400, 390, 10, less than 10

for particle size of less than 0.3, 0.3-2, 2-6, and greater than 6 respectively as compared to an adjacent room where the particle counts were 10,500, 9,800, 585, and 114 for the same respective particle size. Temperature, humidity, and particle size were controlled however carbon monoxide was not. Fifty patients with a variety of diagnoses were measured daily on selected pulmonary function tests. Maximum flow averaged 113 L/min; FeV1, 1.03 L; FEV2, 1.38 L; and vital capacity 1.74 L in the 50 patients studied. On the average, there was an initial improvement following 24 hours within the unit. Pulmonary function then decreased or leveled off for 1-2 days. Gradual improvement throughout the remaining six days was then observed. Analyses of variance was performed between individual days and the observed changes were found to be statistically significant. The critical question which still needs to be answered is whether similar levels of improvement would be observed during residence in other areas of the hospital without the controlled environmental conditions.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0235, INFLUENCE OF AIRBORNE FACTORS ON LUNG CLEARANCE

J. FERIN, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

The alveolar clearance of particles is determined by the physico- chemical properties of the particles (solubility, size, amount) and by a physiological mechanism in which phagocytosis is considered to be an important step. This study should not only increase our knowledge of the mechanism of penetration of particles from the alveoli into the lung interstitium, but should also allow an appraisal of the deleterious effects of a variety of air pollutants on clearance and, therefore, yield a more complete description of the potential hazards associated with airborne particles and gaseous air pollutants. In the experimental procedure the animals (mostly rats) are exposed to TiO2 aerosol and clearance of these particles is measured at different time intervals as the difference between deposition and retention of TiO2 by chemical analysis of the lungs. The clearance rate of the TiO2 particles serves as a test in animals inflicted, experimentally either with defined pathologies or with chronic exposures to air pollutants such as asbestos, SO2, NO and others.

RESULTS: Experimental facts to date are: The relationship between the deposition of TiO2 particles in the lung and the species of animals (lung weight), concentration of TiO2 in the experimental atmosphere and the time of exposure respectively, can be expressed as D equals 2.0105 W.728 C.8405 T.8197 where D equals deposition, W equals lung weight, c equals concentration of TiO2 in inhaled air and T equals exposure to time. Further, the clearance rate of TiO2 particles in animals with experimental emphysema is decreased.

SUPPORTED BY U.S. Atomic Energy Commission

1.0236, CHARACTERIZATION OF EXPOSURE AEROSOLS

T.T. MERCER, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)-49)

A complete definition of the inhalation toxicity of a given aerosol requires a thorough characterization of its particles with respect to their physical and chemical properties. Moreover, the definition must be compatible with methods employed in practice to evaluate environmental hazards. The project is intended to provide details of the physical properties (electrostatic charge, solubility, aerodynamic characteristics) of exposure aerosols in sufficiently general terms that the results may be applicable to past inhalation studies to establish experimentally the relationships which are required in comparing size distributionns based on different types of measurement; and to determine the relative importance of various mechanisms involved in sampling processes in an effort to develop better instrumentation and more accurate methods of data interpretation. Aerosols are produced by the methods commonly used for inhalation studies including some tagged with radon decay products, their activity distributions as a function of aerodynamic diameters are measured with casade impactors and their charges with a parallel-plate charge spectrometer. Shape factors of irregular particles are measured by means of a conifuge. Factors affecting the efficiency of particle collection by jet impactors are assessed by means of special test impactors.

RESULTS: The charges on droplets produced by nebulization have been measured as a function of initial droplet size for sodium chloride- uranine solutions of 0.1, 1.0, and 10.0% by weight. The average number of elementary charges, n, was found to be related to the initial droplet diameter D, in the following way: n equals aDb. The observed values of a and b for the different solutions were: For 0.1% solution, a equals 4.80 and b equals .65 For 1.0% solution, a equals 4.80 and b equals .65 For 10.0% solution, a equals 18.7 and b equals .89

SUPPORTED BY U.S. Atomic Energy Commission

1.0237, INVESTIGATIONS INTO THE TOXICOLOGY OF FLUORIDE

F.A. SMITH, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT-30-1-49)

The threshold limit value (TLV) for an air born contaminant to which industrial workers may be exposed is derived from past experience in the field and from experiments in which animals and occassionally human volunteers are exposed under carefully controlled conditions to the agent of interest. To more adequately understand the nature of the hazards of using a given material, it is helpful to know the nature and the magnitude of the biological response to different atmospheric concentrations of the agent, and to know as much as possible about its mechanisms of action, but such data frequently are meager indeed. This project is intended to determine the lethal concentration 50 (LC50) for hexafluoroacetone, a gaseous chemical potentially useful as an intermediate in organic its mode of action, and to investigate the biotransformations, if any, which it may undergo. The results are expected to permit a more realistic and meaningful assessment of the hazards associated with the compound.

Results: A bench top exposure chamber (Rochester pickle' jar) has been set up, together with the necessary hardware to permit production of hexafluoroacetone-containing atmospheres, and one trial exposure of 4 rats to approximately 300 ppm for 4 hrs. has been made. This concentration proved lethal. Work presently is beeng done on setting up a gas chromatographic method for analysis of the exposure chambers atmospheres.

1.0238, LARGE IRRADIATION CHAMBER STUDIES TO EVALUATE USE OF REACTIVITY SCALES FOR PREDICTING CHEMICAL REACTIVITIES OF HC-NOX MIXTURES

S.L. KOPCZYNSKI, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Complex mixtures of paraffins, olefins, and aromatics and NO in air are irradiated with ultraviolet light under controlled conditions and the ensuing photochemical reaction is followed via chemical analyses. Analyses are performed for some 15 individual hydrocarbons, NO, NO2, total oxidant, ozone, aldehydes and peroxyacyl nitrates. Eye irradiation measurements are obtained for each mixture after 6 hours irradiation. The initial reactant concentrations and the effects of subsequent dilution of reactants are related to various measures of photochemical reactivity, such as production of total oxidant, ozone, NO2, aldehydes, eye irritation, and aerosol formation.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0239, LARGE IRRADIATION CHAMBER STUDIES TO EVALUATE REACTIVITY OF BENZALDEHYDE-NO AIR MIXTURES

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Mixtures of benzaldehyde and NO in air will be prepared in a large irradiation chamber at various concentration levels and in various proportions. The mixtures will be irradiated with ultraviolet light and the ensuing photochemical reaction followed via chemical analyses. The inter-relationship between production of eye irritation, aerosol formation, total oxidant, ozone, NO2,

and other products, and reactant concentrations will be defined. An evaluation of the reactivity of benzaldehyde will be obtained from the preceding measurements.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0240, COMPLETE ANALYSES OF DATA & PREPARE A REPORT OF A STUDY OF PHILADELPHIA IN RELATION TO SOX & PARTICULATE AIR POLLUTION LEVELS

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Mortality data for 1960-1969 have been assembled and analyses initiated relating total deaths and deaths from particular causes to the SOX and Particulate air pollution levels in the area of residence . These studies will be completed and a report prepared during the current fiscal year.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0241, COMPLETE ANALYSIS OF DATA & PREPARE A REPORT ON THE RELATIONSHIP OF SOX & PARTICULATE AIR POLLUTION LEVELS TO SCHOOL ABSENCES IN CINCINNATI

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

During the school year 1967-68, aerometric and meteorological information were collected in Cincinnati together with absence records for all students in 11 schools. Objectives of the study were (1) to determine if absence rates were independent of long-term average pollutant levels or (to determine if absence rates were independent of acute air pollution episodes. Analyses of this data will be completed and a report of prepared during the current fiscal year.

1.0244, COMPLETE A MANUSCRIPT DESCRIBING THE EFFECTS ON HUMAN HEALTH OF CHRONIC EXPOSURE TO LOW LEVELS OF CO

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Pertinent research relating chronic low levels of CO exposure to altered cellular metabolism and resultant decrements summarized in manuscripts suitable for publication in a medical journal. This publication should serve as a source of information for health officials, practicing physicians and other interested individuals.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0245, COMPLETE A STUDY, ANALYZE RESULTING DATA AND PREPARE A REPORT ON THE EFFECTS OF EXPOSURE TO LOW LEVELS OF CO ON EYE-HAND-FOOT COORDINATION

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

A mechanism designed by NASA to test coordination in astronauts is to be utilized to determine possible decrements in human behavioral performance as a function of low level Carbon Monoide exposure.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0246, BIOLOGICAL EFFECTS OF CO ON DOGS WITH EXPERIMENTALLY INDUCED MYOCARDIAL INFARCTS (ABBREV)

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The relative incidence of cardiac arrhythmias will be measured in dogs experiencing myordial infarction and exposed to various levels of CO. CO exposure will be initiated 3 days prior to the infarction and extend for 6 weeks post infarction. Results will be determined on the basis of surveillane in relation to intensity of exposure.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0247, INITIATE A STUDY AND BEGIN COLLECTION OF DATA ON THE EFFECTS OF IN-VIVO EXPOSURE TO CO ON ERYTHROCYTE METABOLISM

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

A laboratory study is to assess the effects of CO on adult and fetal erythrocyte metabolism. The effects of graded exposure on O2 content, CO2 content, pH and 2,3-diphosphoglycerate will be determined.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0248, EFFECT OF AIR POLLUTANTS ON DEVELOPMENT AND PERSISTENCE OF HEMAGGLUTINATING ANTIBODIES AGAINST INFLUENZA VIRUS (ABBREV)

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Oxidant air pollutants are know to inhibit natural defense mechanisms by which animals, including humans, combat other invasive organisms. One possibly significant measure of this impaired defense could be the development and persistance of antibodies produced in response to an exposure to an infective agent. This study will measure antibody response in populations which occur as a result of natural endemic or epidemic exposure to influenza virus. The study and report will be completed during the current fiscal year.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0249, INITIATE A STUDY AND COMPLETE COLLECTION OF DATA RELATING EXPOSURE TO O3 AIR POLLUTION TO ALTERATIONS IN THE BIOCHEMICAL NATURE OF LUNG LIPIDS

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The biochemistry composition of lung lipids is known to change as an organism ages. Similar alterations have been observed in laboratory animals exposed to oxidixing air pollutants. In this study sufficient animals will be exposed to O3 air pollution and then examined and tested for alterations in the biochemical

nature of lung lipids. When changes occur their reversibility will be studied as well as their relations to other evidences of aging.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0250, COLLECTION OF AEROMETRIC, METEOROLOGIC, BIOMETRIC OR OTHER HEALTH INFORMATION IN CHARLOTTE, NORTH CAROLINA
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Air pollution measurements and information on specific health parameters must be collected in the cities included in the HESN by people located in the area. Collection sites are determined by NAPCA staff and instruments are checked and calibrated routinely but periodic collection according to a prescribed regimen are made under contract. Information relative to selected health parameters ar likewise collected by contractors with regular review of activities by the project officer.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0251, A REPORT ON THE RELATIONSHIP BETWEEN NO2 AIR POLLUTION & LOWER RESPIRATORY TRACT INFECTIONS (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Nitrogen dioxide air pollution and lower respiratory tract infection data collection was completed in May 1970 in Chattanooga, Tennessee. The final report of this feasibility study will be prepared by September 15, 1970.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0252, DETERMINE THE VARIABILITY OF REPORTING OF ILLNESS & USE OF HEALTH CARE FACILITIES AS RELATED TO PERCEPTIONS OF ILLNESS (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

A questionnaire prepared in conjunction with Sociologists will be used to identify the factors influencing illness perception and predictions of illness behavior regarding the consultation with physicians and use of health care facilities. This information is necessary because consultation with physicians and use of health care facilities are being used as health parameters being related to air pollution levels.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0253, A REPORT OF SEVERAL AIR POLLUTION PARAMETERS AND THE INTENSITY OF SYMPTOMS IN A PANEL OF ASTHMATIC PERSONS (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

In June 1970 data collection of sulfur oxides and particulate air pollution levels, of meteorological factors and the daily symptoms of asthmatic patients was completed. The final report of this feasibility study that presents the interrelationship of the data will be prepared by October 1970.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0254, COMPLETE ANALYSES OF DATA PREVIOUSLY COLLECTED AND PREPARE A REPORT ON THE RELATIONSHIP BETWEEN SCHOOL ABSENCES AND AIR POLLUTION LEVELS
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Data collection on school absences and air pollution levels was completed in April 1970 in the three cities chosen for particulate levels, namely; Birmingham, Alabama and Charlotte and Greensboro, North Carolina. The final report of this initial project will be completed by January 1971.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0255, ALTERATIONS IN MYOCARDIAL VASCULATURE IN RELATION TO AMBIENT CO LEVELS AS INDICATED BY CARDIOMORPHOMETRIC TECHNIQUES (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

This study will be undertaken to utilize the cardiomorphometric technique for identifying the subtle alterations in the distribution and calibre of myocardial vasculature as they are effected by exposure to CO. These studies should provide a useful method for indicating the effects of CO on humans.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0256, CONTINUE QUANTITATIVE STUDIES OF RAGWEED POLLEN IN SARATOGA SPRINGS, NEW YORK IN RELATION TO DIURNAL VARIATIONS, LOCATION AND OTHER CONDITIONS
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Concentrations and distributions of ragweed pollen were determined during 1968 and 1969. These studies will continue to obtain additional data on diurnal variations in relation to temperature, relative humidity and other meteorological factors. This program is also designed to evaluate the accuracy of various types of collecting equipment.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0257, CONTINUE COLLECTION OF DATA ON THE EFFECT OF CHRONIC EXPOSURE OF BEAGLE DOGS TO SULFUR OXIDES AND PARTICULATE AIR POLLUTION
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Dogs have been exposed to low levels of sulfur oxide pollution on a continuous schedule for a period in excess of 3 years. Studies are designed to determine the effects of this exposure on: a) physiological status of the lungs. b) incidence of myocardial arrhythmias. c) incidence of ischemia as demonstrated by exercise stress. d. incidence of hematological dyscrasias. e) adrenal cortical response (stress adaptation) f) stress response. g) immune competency.

Since the test subjects have just attained full maturity, it is anticipated that detrimental effects of the exposure should become evident within the next year or two. All subjects including suitable controls will be given a series of test in which stress will be induced to facilitate the detection of aberations in the respiratory or circulatory functions. These tests will be conducted twice during the current fiscal year.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0258, PULMONARY FUNCTION IN SCHOOL CHILDREN IN RELATION TO AMBIENT AIR POLLUTION LEVELS (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

This task is a continuation of the effort to identify three cities with a gradient of sulfur oxides levels that are similar in other respects and are amenable to participation in the special studies of the Health Effects Surveillance Network. Busing of students, civil turmoil, and non-cooperativeness of either local health departments or schools have delayed the initiation of this task.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0259, PLAN, DEVELOP EFFECTS OF SOX AND PARTICULATE AIR POLLUTION ON HUMAN HEALTH
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Present and previous study results will be reviewed routinely, and together with current ambient air pollution levels were to be

used to determine the additional investigations needed to provide convincing evidence for the maximum tolerable levels in a chronic exposure situation, relative effects of total exposure vs. peak exposure and the significance of combinations of pollutants or their decay products. These reviews will form bases upon which subsequent program plans will be developed.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0260, COMPLETE A STUDY AND PREPARE A REPORT ON THE EFFECT OF CO ON MYOCARDIAL FUNCTION
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The effects of exposure to low levels of CO on myocardial function will be studied by measurements of systolic time intervals, six-lead simultaneous EKG's and echocardiographic determinations of left ventricular function before, during and following near maximum treadmill exercise. Healthy and ill subjects of various ages will be studied.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0261, PLAN, DEVELOP AND IMPLEMENT STUDIES DESIGNED TO IDENTIFY AND QUANTIFY THE EFFECTS OF AMBIENT LEVELS OF AIR POLLUTION ON HEALTH
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The HESN now includes three cities chosen for a gradient of particulate levels and one conurbation. During FY '71 the Network will be expanded into three additional cities chosen for sulfur oxide levels and into one additional conurbation. This type of investigation should give evidence of particular cause and effect relationships in the cities and give essential baseline data in the conurbations upon which the health effects of improving air quality will be determined in subsequent years.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0262, CONTINUE ACQUISITION OF INFORMATION & COMPLETE DEVELOPMENT OF ASSEMBLY FORMAT OF A MONOGRAPH ON THE HEALTH CONSEQUENCES OF AIR POLLUTION
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The acquisition of relevant bibliographic material will continue and pertinent items will be selected and cataloged. Drafts of three chapters will be completed.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0263, IMMINENT AND SUBSTANTIAL ENDANGERMENT TO HEALTH
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Prepare a report that recommends ambient air levels of a pollutant never to be reached to serve as the basis for the air pollution episode plans. Reports for nitrogen oxides, lead, fluorides, and polynuclear organics will be prepared in FY-1971.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0264, CARCINOGENIC AND MUTAGENIC STUDIES ON ATMOSPHERIC POLLUTANTS
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

To determine the carcinogenicity of fractions of the airborne hydrocarbon as measured in neonatal mice to obtain information needed for determination of air quality criteria and to be used for background for exposure of mature animals to airborne carcinogens by inhalation procedures to be carried on by direct operations.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0265, COLLECTION OF DATA RELATED TO THE CARCINOGENIC POTENTIAL OF HYDROCARBONS & ASSOCIATED POLLUTANTS COLLECTED DIRECTLY FROM THE AIR (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Aromatic polynucleated materials concentrated and removed from air are used in studies of their carcinogenicity. The materials may be painted on test subjects, injected into various tissues, instilled into the nasal passage, or injected into the air they breathe. Young animals may be exposed on several occasions or older animals may be used. Then animals are followed throughout their lives to determine the rates at which cancerous processes develop.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0266, STUDIES DESIGNED TO IDENTIFY AND QUANTIFY THE EFFECTS OF AROMATIC POLYNUCLEATED MATERIALS ON MAN'S HEALTH AND HIS ENVIRONMENT (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Present and previous study results will be reviewed routinely and together with current levels of aromatic polynucleated pollution in the ambient air will be used to determine the additional investigations needed to provide convincing evidence for the maximum levels that can be tolerated in a chronic exposure situation, relative effects of total exposure vs. peak exposure, and the significance of combinations of pollutant or their decay products. These reviews will form the bases upon which subsequent program plans will be developed.

1.0267, INITIATE A STUDY & BEGIN COLLECTION OF DATA ON PHYSIOLOGICAL MECHANISMS BY WHICH PB, CD, OR AS POLLUTANTS AFFECT METABOLIC PROCESSES
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Prison inmates will be exposed to significant quantities of lead or other trace materials following which balance studies will be conducted. The influence of the relevant exposure material on various clinical laboratory findings will be ascertained. This study is conducted in cooperation with API and ILZRO.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0268, COMPLETE A STUDY AND PREPARE A REPORT ON THE EFFECTS OF EXPOSURE TO OXIDANT AIR POLLUTION ON LUNG DEFENSIVE MECHANISMS OF ANIMALS
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Animals will be exposed to oxidant pollutants and determinations made of the effects on cells of the various segments of the air-way, on non-cellular components on the surface active material and in mucociliary mechanisms. The influence of oxidants on the mumber, function and enzyme competence of pulmonary macrophages will be evaluated.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0269, COLLECTION OF DATA ON THE BIOCHEMICAL CHARACTERIZATION OF LUNG SURFACTANT AS IT IS AFFECTED BY EXPOSURE TO AIR POLLUTANTS (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Alterations of lipid profiles in alveolar washings from animal exposed to oxidants will continue to be studied as a prelude to

similar studies in human autopsy material. Profiles will be established also on pulmonary surfactant from humans who volunteer for lung lavage.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0270, COMPLETE A STUDY AND PREPARE A REPORT ON THE IMMUNOLOGIC CHARACTERIZATION OF LUNG SURFACTANT USING IMMUNO-ASSAY TECHNIQUES
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The alveolar lining layer constitutes the greatest interface between man and his environment and consequently, alterations in its composition and function should be one of the earliest effects of exposure to air pollutants. Immuno-assay techniques now being developed in the Medical Research Branch will be applied to animal models and humans as a means of assessing the effects of oxidants on the tissues.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0271, CONTINUE COLLECTION OF DATA ON THE EFFECTS OF CHRONIC EXPOSURE OF BEAGLE DOGS TO NITROGEN OXIDES AND/OR AUTO EXHAUST
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Otfice, *Durham, North Carolina* 27709

Dogs have been exposed to low levels of nitrogen oxides pollution on a continuous schedule for a period in excess of 3 years. Studies are designed to determine the effects of this exposure on: (a) physiological status of the lungs; (b) incidence of myocardial arrhythmias; (c) incidence of ischemia as demonstrated by exercise stress; (d) incidence of hematological dyxcresias; (e) adrenal cortical response (stress adaptation); (f) stress response level; (g) immune competancy)

Since the test subjects have just attained full maturity, it is anticipated that detrimental effects of the exposure should become evident within the next year or two. All subjects including suitable controls will be given a series of tests in which stress will be induced to facilitate the detection of aberations in the respiratory of circulatory functons. These tests will be conducted twice during the current fiscal year

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0272, A REPORT ON THE INFLUENCE OF EXPOSURE TO LOW LEVELS OF OZONE ON THE STRUCTURAL INJURY PRODUCED BY BACTERIAL INFECTIOUS AGENTS (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

This study uses thin sectioned tissue from the lungs of animals exposed to various levels of oxidant air pollutants and then to pathogenic bacteria to determine by light and electron microscopy, the pathology produce by the exposure.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0273, INITIATE A MORBIDITY STUDY OF ALTERATIONS IN LUNG STRUCTURE ASSOCIATED WITH EXPOSURE TO AIR POLLUTANTS AS INDICATED BY LUNG MORPHOMETRY
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

This study will be concerned with determining early changes in structures compatible with those found with chronic bronchitis or emphysema which can be found and associated in a significant fashion with air pollution exposure history.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0274, A STUDY OF ACUTE RESPIRATORY ILLNESS IN RELATION TO NITROGEN OXIDES AIR POLLUTION LEVELS IN CHATTANOOGA, TENNESSEE
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Illness data and aerometric data have been collected to determine the relationships between acute respiratory illness in the local population and the ambient level of nitrogen oxides produced by emission from a munitions producing plant.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0275, STUDIES DESIGNED TO IDENTIFY & QUANTIFY THE EFFECTS OF OXIDANT, NOX AND HYDROCARBON AIR POLLUTANTS ON HUMAN HEALTH (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Previous and present study results will be reviewed routinely and together with current levels of Oxidant pollution in the ambient air will be used to determine the additional investigations needed to provide convincing evidence for the maximum levels that can be tolerated in a chronic exposure situation, relative effects of total exposure vs. peak exposure and the significance of combinations of pollutant of their decay products. These reviews will form the bases upon which subsequent program plans will be developed.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0276, CONTINUE COLLECTION OF DATA ON THE EFFECTS OF CHRONIC EXPOSURE OF BEAGLE DOGS TO CARBON MONOXIDE
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Dogs have been exposed to low levels of CO pollution on a continuous schedule for a period in excess of 3 years. These studies are designed to determine the effects of exposure on: (a) physiological status of the lungs; (b) the incidence of myocardial arrhthmias;(c) the incidence of ischemia as demonstrated by exercise stress (d) incidence of hematological dyscrasias (e) adrenal cortical responses (stress adaptation) (f) stress response level (g) immune competency.

Since the test subjects have just attained full maturity it is anticipated that detrimental effects should become evident within the next year or two. All subjects including suitable controls will be given a series of tests into which stress will be introduced to facilitate the detection of aberrations in the respiratory or circulatory function. These tests will be conducted twice during FY 71.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0277, ALTERATIONS IN DISTRIBUTION & CALIBRE OF MYOCARDIAL VASCULATURE EXPOSED TO CO DETECTED BY CARDIOMORPHOMETRIC TECHNIQUES (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Subtle alterations in lung structure and in cardiac structure may be expected to occur as a result of exposure to air pollution. Techniques for quantitation of such alterations are not available; however, it is expected that alterations in distribution and calibre of myocardial vasculature could be measured by cardiomorphometric techniques.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0278, A REPORT ON THE RELATIONSHIPS AMONG O2 UPTAKE, CO EXPOSURE, O2 CARRYING CAPACITY OF BLOOD AND EXERCISE (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The effects of CO exposure on blood oxygen carrying capacity will be determined at graded leveds of exercise in normal subjects. These data will enable one to calculate and predict hypoxic insult on an individual once the extent of exercise and exposure history are known.

1. AIR QUALITY

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0279, COMPLETE COLLECTION OF ANALYSES OF DATA ASSOCIATING HEALTH EFFECTS WITH EXPOSURE TO PB, AS, OR CD EMISSIONS FROM SMELTERS IN MONTANA & IDAHO

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

A number of trace metals are emitted into the atmosphere from non- ferrous smelters. This study is designd to determine the ambient levels of some of these mate.ials and indications of health effects in people exposed to them.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0280, COLLECTION OF AEROMETRIC, METEOROLOGIC, BIOMETRIC OR OTHER HEALTH INFORMATION IN GREENSBORO, NORTH CAROLINA

UNKNOWN, Guilford Co. Health Department, *Greensboro, North Carolina*

Air pollution measurements and information on specific health parameters must be collected in the cities included in the HESN by people located in the area. Collection sites are determined by NAPCA staff and instruments are checked and calibrated routinely but periodic collection according to a prescribed regimen are made under contract. Information relative to selected health parameters are likewise collected by contractors with regular review of activities by the project officer.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0281, AIR POLLUTION AND RESPIRATORY INFECTIONS

Q.N. MYRVIK, Wake Forest University, School of Medicine, *Winston Salem, North Carolina* 27103

The research project is directed towards a study of the effect of selected air pollutants on naturally occurring respiratory infections which are of a low grade chronic nature. It is postulated that low grade chronic respiratory infections can lead to pathologic changes which are an important component of air pollution disease. It is further postulated that air pollutants lower the resistance of the respiratory tract which in turn leads to infections by normal flora microorganisms and organisms in the immediate environment. Experiments will be carried out by exposing rabbits and squirrel monkeys to acute and chronic exposure patterns of air pollutants. The qualitative and quantitative aspects of the respiratory flora will be studied with respect to associated pathologic changes.

The following topics represent the specific aims of this research proposal. 1. Determine Respiratory Flora and Index of Respiratory Infections in 'Normal' Rabbits and Squirrel Monkeys. 2. Effect of Selected Air Pollutants on the Quantity of the Microbial Flora of the Respiratory Tract of Rabbits and Squirrel Monkeys. 3. Effect of Selected Air Pollutants on the metabolism, Phagocytic Activity and Hydrolase Levels of Alveolar Macrophages. 4. Effect of Selected Air Pollutants on the Capacity of Alveolar Macrophages of Rabbits and Squirrel Monkeys to support Viral Replication and Capacity to Produce Interferon.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0282, PHAGOCYTOSIS AND BACTERIAL KILLING BY ALVEOLAR MACROPHAGES

C.L. VASSALLO, U.S. Veterans Administration, Hospital, *Cincinnati, Ohio* 45220

The aim of this program is to establish a method whereby bacterial killing and bacterial entry can be determined simultaneously in R.A.M. This method will then be used to investigate the rate of killing of bacteria by alveolar macrophages and to compare this rate with that noted in leukocytes. The effect of alcohol, nitrogen dioxide ion, nitrogen dioxide gas, aminotriazole, and other agents that have been demonstrated to alter peroxide metabolism and by virtue of this might be expected to impair bacterial killing will be noted. Other air pollutants such as sulfur dioxide and drugs suspected of impairing defense mechanisms will also be investigated.

Progress has been limited to the acquisition of the equipment necessary and the recent hiring of a technician whose primary job will be to work on this project. Laboratory space also has been renovated and it is estimated that work will begin prior to the end of June 1970.

SUPPORTED BY U.S. Veterans Administration

1.0283, EYE IRRITATION RESPONSE MEASUREMENTS FOR EVALUATION OF PHOTOCHEMICAL REACTIVITIES OF HYDROCARBON-NO-AIR AND BENZALDEHYDE-NO-AIR MIXTURES

S.L. KOPCZYNSKI, Univ. of Cincinnati, School of Medicine, *Cincinnati, Ohio* 45221

This contract will provide appropriate medical supervision for eye irritation studies carried out as an integral part of the large irradiation chamber studies under tasks 03 and 04. An evaluation of eye irritation as a measure of photochemical reactivity and smog intensity will be made.

The studies involve reactants and reaction products found in the atmosphere and include various hydrocarbons, aldehydes solvents, nitric oxide, nitrogen dioxide, sulfur dioxide, peroxyacylnitrates, and oxidants.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0284, CONTINUE STUDIES OF HUMAN BLOOD LEAD LEVELS IN RELATION TO ATMOSPHERIC LEAD LEVELS

UNKNOWN, Univ. of Cincinnati, Graduate School, *Cincinnati, Ohio* 45221

In cooperation with the American Petroleum Institute and the Automobile Manufacturers of America through the auspices of CRC-APRAC, this cooperative study is designed to determine the relationship between blood lead levels, and extent of exposure to automobile exhaust products.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0285, GAS-OFF STUDIES ON NONMETALLIC MATERIALS USED IN AIR FORCE SYSTEMS

D.L. GEIGER, U.S. Air Force, Aerospace Med. Res. Lab. 6570, *Dayton, Ohio* 45433

Technical Objective: Detect, characterize, and quantitate the volatile contaminants that evolve from nonmetallic materials of interest to the Air Force, provide chemical data and generation rates of contaminants for use in establishing the toxic potential of materials used in habitable portions of aircraft, and other restricted environments such as launch control centers and missile silos.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0286, EFFECTS OF AIR FORCE PROPELLANTS ON THE METABOLISM AND BIOCHEMISTRY OF BODY ORGANS

M.E. GEORGE, U.S. Air Force, Materials Laboratory, *Dayton, Ohio* 45433

Technical Objective: Air Force function - fueling operations with hazardous materials. Deficiency - human tolerance criteria and limits for new toxic chemicals. Research - mechanisms of toxicity of compounds in body tissues and fluids. How research contributes - provides toxicological definition for formulation of safe and habitable aeronautical and ballistic weapon systems. To determine the effects of altered atmospheres, atmospheric contaminants, and various propellants on the metabolism and biochemistry of various organs in experimental animals. Animals will be exposed to potentially toxic compounds and atmospheres by injection. The metabolic and biochemical effect will be evaluated by determining the functional integrity of target organs, principally liver, kidney and brain. Finally, basic mechanisms of action of the toxicant on the organs will be evaluated.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0287, OCCUPATIONAL HEALTH HAZARDS OF RUBBER DUST
C.A. NAU, Univ. of Oklahoma, School of Medicine, *Oklahoma City, Oklahoma* 73104

The purposes of the proposed investigation are to: A. To continue the ongoing chronic inhalation studies in order to have a realistic and significant duration of total exposure by inhalation. B. Evaluate the developmental effects of chronic exposure to respirable rubber tire dust by exposing Rhesus Monkeys from birth to maturity. C. Elucidate the physiological effects of ingestion of rubber tire dust. D. Determine if any 3,4 benzpyrene (absorbed on the carbon black which is a component of the rubber tire dust) can be detected and/or quantitated in the excreta or urine of rats eating rubber tire dust. Consideration will also be given to the deposition of this carcinogen in some organ or tissue. Metabolites of 3,4 benzpyrene will also be considered.

1.0288, EFFECTS OF AIRBORNE FLUORIDES ON ANIMAL NUTRITION AND METABOLISM
F.W. ADAMS, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00919)

OBJECTIVE: Determine effects of chronic airborne HF gas upon lungs, growth, reproduction, tissue fluoride storage, trace element metabolism and enzyme activity in small animals. Examine possible interaction between HF and other air pollutants. Improved method of soil fluoride analysis and HF sampling, and provide capability for fluoride analytical service.

APPROACH: Several generations of experimental animals will be continuously exposed to airborne HF contamination of themselves and their environment, drinking water excepted. Lungs will be histologically examined, whole body x-rays taken, and tissue fluoride analyses run at appropriate growth stages. Tissue levels of some trace elements and ceruloplasmin activity to be determined following HF exposures.

PROGRESS: Two generations of a continuing series of hamsters have been born and raised to adults in 1 ppm HF atmosphere. Distilled drinking water is ad lib while food is exposed to HF. Growth rates appear normal. Decay and mottling of incisor teeth prevalent in F(1) generation adults did not appear in young F(2). F(1) adults examined at 13 and 26 wks had femur fluoride contents of 3376 and 3750 ppm dry weight respectively, compared to controls of 243 ppm. Femur fluoride contents of F(2) generation were 2516, 2000, and 2125 ppm at 3, 5, and 7 wks. Food pellets increase their F content by 20 ppm during a 72 hour exposure period in the chamber. Femur fluoride contents of 855 ppm were found in 6 adult hamsters exposed to 3 ppm HF for 30 days. Whole body x-rays of normal various experimental animals are being examined. Lung and bronchial tissue have been obtained for histological examination.

1.0289, EXPLORING STATISTICAL RELATIONSHIPS BETWEEN AIR POLLUTANTS AND CERTAIN CHRONIC DISEASE MORTALITY RATES
UNKNOWN, Univ. of Pennsylvania, Graduate School, *Philadelphia, Pennsylvania* 19101

No summary has been provided to the Science Information Exchange.

SUPPORTED BY Resources for Future Inc. - Wash., D.C.

1.0290, ABSORPTION OF POLLUTANTS IN THE RESPIRATORY TRACT
M. CORN, Univ. of Pittsburgh, School of Public Health, *Pittsburgh, Pennsylvania* 15213

The absorption of pollutant gases (SO2, NO2, C2H4O, and oxidant) in the respiratory tracts of anesthetised, artificially ventilated cats is being measured by means of a retrograde catheter technique. An automatic sampling system permits gas sampling prior to entry into the respiratory tract and from the catheter during inhalation or exhalation. Variables being investigated are pollutant concentration (0.1 - 20 p.p.m.) respiratory frequency (15 - 30 cps) and tidal volume (25 - 75cc in cats). Results should permit one to estimate the dosage of inhaled pollutants to different segments of the respiratory tract and thus assist with interpreting receptor responses and disease sites.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0291, BRITISH-NORWEGIAN MIGRANT STUDY
J. CORNFIELD, Univ. of Pittsburgh, School of Public Health, *Pittsburgh, Pennsylvania* 15213

The primary objectives of the parent study based in the London School of Hygiene with Donald Reid as Principal Investigator are: 1) to determine the relative frequency of morbidity and mortality, especially from various forms of cardiorespiratory disorder, among British and Norwegian migrants in the United States, their siblings still living in their native countries, and the native-born populations living in those areas in which the migrants lived either before or after migration; 2) to relate the disease experience of these groups to both personal factors, such as smoking and occupation, and general factors, such as air pollution levels in the area of residence; 3) to establish time relationships between disease experience and date of migration, changes in habits, or occupations; and 4) to identify possible explanations for the major differences in national death rates.

Present proposal is concerned with rounding off the mortality experience, particularly with respect to chronic respiratory disease, for which it is felt that 2 additional years of experience are required.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0292, STUDY OF UPPER RESPIRATORY TRACT CLEARANCE IN RATS
J.A. WATSON, Univ. of Pittsburgh, School of Public Health, *Pittsburgh, Pennsylvania* 15213

Studies in this laboratory resulted in the development of an esophageal collection procedure in rats which permits the serial collection of all material (particles, phagocytes, mucous, etc.) removed from the lungs via the tracheal orifice and swallowed. Based on this procedure we have developed techniques for measuring: (1) the tracheobronchial clearance rates of particles from the lungs, (2) the density distribution functions of particles along the trachea, (3) the velocity of the mucociliary escalator in the trachea, (4) the numbers of pulmonary macrophages leaving the lungs via the tracheal orifice, and (5) the functional role of pulmonary macrophages in transporting particles from the lungs to the oropharynx. These methods provide in vivo data in the rat without requiring surgery on any portion of the pulmonary system.

Our research objectives are to characterize these parameters and their interrelationships under normal conditions and under various conditions of stress (dusts, noxious gases, bacteria and metabolic stimuli) to be pulmonary system. We hope to achieve an understanding of the basic physiological and homeostatic mechanisms which apply in mammals to the clearance of particulates from the lungs and to utilize this information in the realistic appraisal of the hazard associated with the inhalation of respirable dusts and air pollutants in mane.

1.0293, BIOLOGICAL EFFECTS OF AIR POLLUTANTS ON MAMMALS
R.A. RHOADES, Penn. State University, Inst. of Science & Engineering, *University Park, Pennsylvania* 16802

Our primary objective was to determine whether or not known low level concentrations of air pollutants, singularly or in combination, can cause biological damage to animals exposed for prolonged periods under known environmental conditions.

Accordingly, a large group of mice (N equals 400) and rats (N equals 100) were continuously exposed for 9 months in stainless steel exposure chambers. Temperature and relative humidity were controlled between 72-74 degrees F and 40-65%, respec-

tively. Water and food were supplied ad libitum. Under the above conditions, one group of animals was exposed to an average concentration of 545 micrograms/m super 3 (plus or minus 193 SOD) particulate (carbon black). The mass median diameter was 1.8mu. A second group was exposed to NO2 with an average concentration of 2.9 parts per million (plus or minus sub 71 S.D.). The third group received NOsub 2 plus carbon particulate averaging 3.1 parts per million (plus or minus 0.81 S.D.) and 532 micrograms/m super 3 (plus or minus 219 S.D.), respectivtely. A fourth group serve as controls, and received ambient air.

From our exposure regimen, the data analyzed thus far indicates that: 1) exposure to NO super 2 and to NO super 2 plus carbon appears to increase the incidence of early lung tumors in AJ mice after 80-100 days; 2) carbon and carbon plus NO super 2 affects the immune response of Balb/c mice with very pronounced immuno-suppressive effects occurring after long periods of exposure; and 3) elastic properties of lungs were not significantly altered when rats were exposed to NO super 2 and carbon singularly, but were markedly affected when the pollutants were in combination.

1.0294, EFFECTS OF LOW LEVELS OF LEAD ON PROTEIN SYNTHESIS

W.R. FARKAS, Univ. of Tennessee, Memorial Res. Center & Hosp., *Knoxville, Tennessee* 37920

Lead has been shown to inhibit protein synthesis by rabbit reticulocytes concentrations as low as 1.0 mu. Although a great deal has been learned about the steps involved in protein synthesis, the precise point in this process which is so sensitive to lead, has not yet been determined. The objective of this proposal is therefore to uncover the mechanism of the inhibition of protein synthesis by lead.

The depolymerization of RNA by lead in vitro has been demonstrated. There is no knowledge, however, as to the effects of lead on RNA in vivo. In order to determine the effects of lead on the different types of RNA in vivo, the integrity of polyribosomes, the molecular weight of RNA, and the acceptance of capacity of transfer RNA will be compared for RNA obtained from normal cells and for cells exposed to low levels of lead.

Cells other than reticulocytes may also be sensitive to lead. Furthermore, nothing is known about the sensitivity of human erythroid cells and other human cell types to this substance. Lead is a component of most gasolines and an atmospheric contaminant. Therefore, this study could also give some indication as to the degree to which cellular RNA is degraded and protein synthesis is impaired by atmospheric lead.

1.0295, AIR POLLUTION TRAINING PROGRAM

H.G. APPLEGATE, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX01417)

OBJECTIVE: This program will be to train personnel within general field of air pollution. Primary academic and research training will be in the biological and meterological aspects of air pollution.

APPROACH: Training and research will be conducted in areas of long-term chronic injury. Much of the training and research in air pollution in the biological area is concerned with pollutant concentrations high enough to induce visible injury. Work with pollutant concentrations which may induce physiological and genetical disorders without inducing visible injury.

PROGRESS: This program is being phased out. Three trainees remaining in the program are in the Departments of Plant Sciences, Wildlife Science and Biochemistry and Biophysics. Their research interest are on the effect of fluoride on anthocyanins, the effect of pesticides on wildlife and the effect of SO(2) on polynuclear aromatic hydrocarbons, respectively.

1.0296, PUBLIC HEALTH ECOLOGY

C.M. BARNES, U.S. Natl. Aero. & Space Adm., Manned Spacecraft Center, *Houston, Texas*

The Public Helth Ecology Program is designed to determine through several pilot studies the usefulness of aircraft and ultimately satellite remote sensing in defining public health problems and suggesting remedies through a gross geopathologic analysis. Specifically, NASA multispectral sensing data will be used in determining environmental pollution of water and air and how these pollutants affect the health of the local populace. Insect growth as related to local climatological conditions will be studied and plans developed for assisting eradication officials in combating these plagues. The investigator shown above is the Project Monitor whose telephone is 713-483-4251.

1.0297, BIOCHEMICAL EFFECTS OF SIMULATED AIR POLLUTANTS

F.L. ESTES, U.S. Veterans Administration, Hospital, *Houston, Texas* 77031

Of necessity to the further exploration of the biochemical effects of simulated air pollutants, efforts have been directed to 1) development and evaluation of a synamic gas mixing system for the delivery of known concentrations of trace components in a carrier gas stream (presented 156th Meeting Am. Chem. Soc., Atlantic City, Sept. 1968), and 2) the development of valid analytical procedures for the direct determination of components in biochemical systems. Quantification of lactic and pyruvic acids from biological samples has been presented (Southwest Regional Meeting, Am, Chem. Soc., Austin, Texas, Dec. 1968). The analysis of mixtures of glutamic and alphaketoglutaric acids by infrared spectroscopy is quantitative in the micromole range (J. Applied Spectroscopy).

The development of these techniques, along with those previously established, should provide for valid comparison of relative effectiveness of pollutant mixtures, as well as indicate those biochemical changes that may be significant in the subsequently developing pathologic changes.

1.0298, PERFORMANCE, RECOVERY, AND MAN-MACHINE EFFECTIVENESS

R.A. DUDEK, Texas Technoiogical University, School of Engineering, *Lubbock, Texas* 79409 (DAAD05)

To determine man's ability to perform for long periods of time and to recover from such performance. Environmental, task and organizational variables affecting several conceptualized man-machine systems will be studied. Means of sustaining performance and speeding recovery will be investigated. Basic data on human performance and recovery will be used to evolve criteria for insuring efficient performance in small military units-also used in implementing a doctrine of continuous operations.

SUPPORTED BY U.S. Dept. of Defense - Army

1.0299, ESR STUDIES OF BIOCHEMICAL EFFECTS OF ATMOSPHERIC POLLUTANTS

J.R. ROWLANDS, Southwest Research Institute, *San Antonio, Texas* 78228

This study is aimed at studying effects of cigarette smoke upon biological systems by electron spin resonance spectroscopy and optical spectroscopy. During the initial year, results have included the detection and characterization of an in vivo reaction between cigarette smoke and hemoglobin, and the detection and characterization of four free radicals produced by the interaction of NO2 and various biological lipids. Those results have been described in two separate publications (J. R. Rowlands, R. M. Estefan, E. M. Gause, and D. A. Montalvo, Environmental Research 2, 47-71, 1968; R. M. Estefan, E. M. Gause, and J. R. Rowlands, 'Electron Spin Resonance and Optical Studies of the Interaction between NO2 and Unsaturated Lipid Components', in press, Environmental Research, 1969). In addition, studies have been made of the effects of cigarette smoke and nitrogen oxides upon the respiratory chain component, cytochrome c.

A new line of experimental effort is being initiated with the beginning of the second year of research. Thus study is designed to observe short-lived free radicals present in cigarette smoke and

the fate of these radicals and other smoke components upon contact with the lung/blood system. A unique L-bank ERS spectrometer built in-house by SwRI will be utilized for this work.

1.0300, TRACE CONTAMINANTS ASSOCIATED WITH MAN IN AIR FORCE SYSTEMS
J.P. CONKLE, U.S. Air Force, School of Aerospace Med., *San Antonio, Texas* 78235

Technical Objective: Closed cycle environmental control systems, requiring no direct contact with the surrounding atmosphere, provide one approach to sustaining life in advanced aircraft and in selected phases of retaliatory missile weapon systems operations. Closure of an environment necessitates monitoring and removing atmospheric contaminants which arise from materials, equipment and from body metabolism. Failure to remove the contaminants will result in shortened effective mission duration or crew performance decrements coupled with impaired health. Since man himself is one of the major sources of contaminants, a comprehensive study of the gaseous constituents associated with man is requisite to the design of effective environmental control systems. This effort will measure human generated trace contaminants.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0301, PERFORMANCE DECREMENTS IN AIR CREWS EXPOSED TO CONTAMINATED LIFE SUPPORT GASES
R.L. MILLER, U.S. Air Force, School of Aerospace Med., *San Antonio, Texas* 78235

Technical Objective: Contaminated breathing oxygen is frequently used as an excuse for terminating flying missions, and occasionally as an explanation for aircraft accidents when no other causative factor can be found. In both cases, unit commanders and flight surgeons have subjective criteria upon which to base decisions with regard to continued flying operations. The purpose of this work unit is to examine the physiologic effects and determine objective performance decrements caused by exposure of mammalian systems to common oxygen contaminants at concentrations above use limits. This study will provide flight surgeons with definitive data regarding the probability of pilot malfunctions due to exposure of certain contaminants.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0302. ENVIRONMENTAL ASSESSMENT OF AIRBORNE COTTON AND FLAX DUSTS
M.H. NOWEIR, Alexandria University, *Alexandria, United Arab Republic*

Byssinosis is a lung disease prevalent in the cotton and flax industries. Control of the disease requires that exposure of workers to vegetable dust be maintained at a safe level. To date it has been impossible to establish direct relationships between total dust concentrations and the incidence or absence of the disease. There is evidence that only certain parts of cotton and flax plants contain a biologically-active material (capable of releasing histamine from lung tissue) which may be causally related to the disease.

This research will attempt to isolate and identify the hygienically significant biological activity of fractions and sub-fractions of the dusts in the cotton and flax industries. The biological activity will be related to the physical, chemical and aerodynamic characteristics of the air-borne dust, as well as to the incidence and severity of byssionosis as measured from periodic medical examinations on new, regular and retired employees. If significant relationships can be established, it will be possible to utilize meaningful criteria for evaluating the environment to control and prevent this lung disease.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0303, A LONGITUDINAL CORRELATION OF PULMONARY FUNCTION STUDIES WITH PATIENTS HISTORY
L.G. MAY, U.S. Veterans Administration, Center, *Hampton, Virginia* 23367

Purpose of this study is to determine the relationship, if any, to pulmonary function tests including the use of body plethysmograph for airway resistance and the history and duration of exposure to pollutants in the atmosphere.

A special type of pulmonary history and physical has been devised and will be used by the investigator in patients referred for routine arterial blood gases and pulmonary function studies.

An attempt will be made to find by history, any exposure to toxic material which occurred 20 years or so ago.

50 patients will be used at first, the duration of the study will be less than one year. Unselected patients will be used in sequence from ward consults and outpatient requests.

The history and physical examination will be done during the time the patient is resting prior to the pulmonary function procedure.

The cost of this study will be the investigator's time and the cost of printing 100 copies of the 'Respiratory System Questionnaire'.

SUPPORTED BY U.S. Veterans Administration

1.0304, AIR POLLUTION EFFECTS ON AIRBORNE RESPIRATORY DISEASE
J. MCCARROLL, Univ. of Washington, School of Medicine, *Seattle, Washington* 98105

Studies are now underway in the Division of Environmental Health on the effect of common urban air pollutants on airborne respiratory disease, using specially designed controlled environment animal exposure chambers. Support is requested for two related objectives: first, to continue the studies on the role of air pollutants in modifying susceptibility to infection, and, second, to determine the interrelationships between air pollutants and other environmental factors (temperature and relative humidity) on the pathogenesis of airborne respiratory infection.

The studies on the role of air pollutants in acute respiratory disease use the mouse-influenza airborne infection model developed by Schulman and Kilbourne. Exposing colonies of mice to nebulized influenza virus, the number infected can be shown to be related directly to the concentration of aerosolized virus when temperature and humidity are held constant. Using this model, animals will be exposed to common urban air pollutants, such as sulfur dioxide, particulates, nitrogen dioxide, and ozone, either before or during virus aerosol exposure, to determine the effects of pollutants singly and in combination on infection rates and parameters related to virulence of infection. The roles of cold, heat, and humidity will also be studied in relation to the various pollutant combinations.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0305, HUMAN ADAPTATION OF CARDIO-PULMONARY FUNCTION TO HYPOBARIC, AQUATIC AND INDUSTRIAL ENVIRONMENTS
J.A. DEMPSEY, Univ. of Wisconsin, School of Medicine, *Madison, Wisconsin* 53706

It is the purpose of this project to determine the interrelationship of cardiac respiratory homeostatic control mechanisms during man's adaptation to hypobaric, aquatic and industrial environments. Underlying this application is the aim of revising a method (inert gas technique) we have already established for simultaneous measurement of cardiac out-put, pulmonary capillary blood volume and alveolar-capillary diffusion. Specifically the aims are as follows:

1. Hypobaric Environment. (a) To determine the time course of cardiovascular and ventilatory acclimitization over 8 to 10 hours of exposure to simulated altitudes of 2000 to 3000m i.e. levels of hypoxia where acute exposure of 20 to 30 minutes produces no measurable cardiovascular adaptation. (b) To determine the contribution of changes in total blood volume, cardiac

output and stroke volume with hypoxic exposure to increases in resting and exercise pulmonary diffusing capacity and capillary blood volume. 2. Aquatic Environments. To assess departures from linearity in the relationship of cardiac output to metabolic rate which occur with the relative bradycardia of water immersion and work, with separation of postural and aquatic influences. As stated above in 1.(b) for hypoxic environments, contributions of a changing cardiac output to pulmonary capillary bed expansion with immersion (rest and work) will also be determined. 3. Industrial Environments. To determine the relationship of ventilatory and cardiovascular adaptations to manual, semi-skilled work in the industrial environment, including laboratory and 'on the-job' analyses of work with varying muscle groups, work under varying environmental (seasonal) temperatures, effect of work 'shift' change on cardio- pulmonary diurnal variations, and of work under both acute and chronic effects of industrial air pollutants.

C. EFFECTS - ANIMAL, PLANT, AND GENERAL ENVIRONMENT

Studies of Air Pollution Effects on Livestock, Vegetation, Crops, Materials, and Structures. Includes Deterioration, Corrosion, and Other Deleterious Effects.

1.0306, EFFECT OF ATMOSPHERIC POLLUTANTS UPON DISEASE SUSCEPTIBILITY IN CHICKENS AND QUAIL

R.N. BREWER, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA00292)

OBJECTIVE: Determine the effects of different concentration of atmospheric gases and particles common to poultry houses on susceptibility of birds to poultry pathogens.

APPROACH: Germfree Trexler units will be used to provide controlled environment for study. Chickens and quail will be subjected to measured quantities of gaseous pollutants under germfree and gnotobiotic conditions. Histopathological and physiological techniques will be used to measure the effects of these adverse environmental conditions on the health of the bird.

PROGRESS: Three separate trials using artificial and contact exposure to the G(A) isolate of Marek's disease (MD) have indicated a direct influence of B blood group allelee on mortality from MD. In a large trial involving 1,800 birds, 46% of all birds inoculated intraabdominally died of Marek's disease by 18 weeks of age compared to 31% of naturally infected birds. In this trial MD mortality ranged from 20% to 61% among blood types. Attempted sterilization of the incubator environment with ultra violet rays did not influence the rate of MD mortality. A germfree laboratory has been developed to study disease- environment interrelationships. Plastic Trexler units will be used in conjunction with modified Horsfall-Bauer units in an attempt to establish definite levels of atmospheric pollutants and control the spread of specific disease agents. Level of atmospheric pollutants will be achieved by use of flowmeters and monitoring of exhaust gasses.

SUPPORTED BY U.S. Dept. of Agriculture

1.0307, ACOUSTIC RADAR INVESTIGATION OF ARCTIC RADIATION INVERSIONS AND ICE FOG

C.R. WILSON, Univ. of Alaska, School of Mathematics, *College, Alaska* 99735

The rapid growth and development of the community of Fairbanks has brought with it many of the problems inherent in typical industrial communities throughout the world. Air pollution is one such problem. At Fairbanks, as in other industrial communities in the Arctic, air pollution during the winter months manifests itself primarily as ice fog. These fogs are troublesome, as well as distinctly disagreeable to human comfort, because they frequently reduce visibility sufficiently to hamper both aircraft and automobile operation. The meteorological situations of extreme cold (below -40degrees C) and great air stability which allow the formation of ice fog also permit stagnation and high concentration of other pollutants, such as combustion products, in the lower atmosphere over Fairbanks. The proposed research will take advantage of recent research which has shown that acoustic echoes can be rapidly obtained from the natural occurring temperature eddies and velocity fluctuations existing in the boundary layer of the atmosphere. Two acoustic sounders will be used to study the structure and motions of the inversions layer over Fairbanks. The research will be undertaken by the University of Alaska and National Oceanic and Atmospheric Administration (NOAA) Environmental Research Laboratories, Boulder, Colorado. An interagency agreement will cover the NOAA participation.

SUPPORTED BY U.S. National Science Foundation

1.0308, BIOLOGY AND CONTROL OF DISEASES OF CONIFER FORESTS OF CALIFORNIA AND HARDWOOD FORESTS OF HAWAII

R.V. BEGA, U.S. Dept. of Agriculture, Pac. Sw. For. & Rg. Expt. Sta., *Berkeley, California* (PSW2301)

OBJECTIVE: Determine the epiphytology of the biotic and abiotic agents causing diseases of forest tree seeds, seedlings, and both young and mature trees.

APPROACH: Develop controls for mistletoes parasitizing conifers on timber producing and recreational areas in California; determine recreation site pathology and hazard control needs on forested sites west of the Mississippi River; determine the biology of and develop controls for the major root diseases of California conifers and Hawaii hardwoods; calibrate western conifers for susceptibility to air pollution.

PROGRESS: An aerial survey of the San Bernardino National Forest showed that 1.3 million ponderosa pine trees encompassing 160,000 acres are being killed or injured by air pollution. A multi-stage probability sampling design and large-scale color aerial photographs were used. Cost of the survey was about 3 cents per acre. Continuous air monitoring at 6,000 feet elevation near Lake Arrowhead, California, showed average high readings of 0.30 ppm ozone with one daily high reaching 0.52 ppm. The standard set for plant damage is 0.10 ppm, and 0.50 ppm is the standard for a smog alert in Los Angeles. A survey of the major air basins of California shows smog injury to forest trees is quite widespread. The most severe injury was found in the south coast air basin and parts of the southeast desert basin. Slight injury was found in the north central coast, San Francisco Bay, San Diego, and San Joaquin Valley air basins. A study of the rate of spread of the forest tree root disease Fomes annosus was conducted on seven National Forests and one State Forest throughout the State. Average linear extension of the damage within infection centers was found to be 3.5 feet/year except on the San Bernardino National Forest, where spread was 8.4 feet/year. The largest infection centers found were on the Cleveland National Forest. Some were over 100 acres in size. The study will enable pathologists to predict losses in an area in a given time period.

1.0309, STRUCTURES AND EQUIPMENT TO MINIMIZE STRESS ON BEEF CATTLE

T.E. BOND, Univ. of California, Agricultural Engin. Res. Div., *Davis, California* 95616 (312-020-B225)

OBJECTIVE: Develop design criteria for structures and related equipment that will minimize environmental stress of beef cattle.

APPROACH: In air conditioned research barn at the University of California Experiment Station at El Centro obtain basic bioengineering data relating the influence of various environmental factors to the physiological responses and growth of beef cattle. In beef cattle pens at Davis and El Centro, investigate the effects of mud, wind, rain, dust, temperature, humidity, etc. on growth of beef cattle and develop methods of management and equipment that will minimize stress from these environmental factors and maximize productivity. Measure and map radiant fluxes from sky, ground and surroundings and investigate their effects on design and orientation of beef cattle shelters.

PROGRESS:

SUPPORTED BY U S. Dept. of Agriculture

1.0310, ULTRAVIOLET RADIATION IN A POLLUTED ATMOSPHERE
K.L. COULSON, Univ. of California, School of Agriculture, *Davis, California* 95616

This is a continuation of an investigation of the effects of atmospheric pollutants on the ultraviolet radiation regime of the atmosphere. Measurements of the polarization and intensity of ultraviolet radiation have been made in the polluted atmosphere of Los Angeles and in carefully selected clear atmospheric conditions at Davis. These two sets of measurements are being compared with each other and with results obtained from the application of radiative transfer theory to appropriate atmospheric models. The main effort during this grant period will be on analysis and interpretation of the results which have been obtained from the measurement program.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0311, EFFECT OF SO2 ON METABOLIC PATHWAYS IN HIGHER PLANTS
M. MAZELIS, Univ. of California, School of Agriculture, *Davis, California* 95616

Studies on the effect of SO2 and its hydrated forms on the amino acid metabolism of higher plants has continued. A new enzyme, L-proline dehydrogenase, has been found in extracts of peanut cotyledons. This enzyme uses NAD as an electron acceptor in the oxidation of proline. This enzyme is very sensitive to the presence of bisulfite ion. In the presence of 1 mM bisulfite, the conversion of radioactive L-proline to its product is completely inhibited. The purification of this enzyme is underway so that the mechanism of this inhibition can be more clearly understood.

Future experiments call for the feeding of radioactive amino acids concurrently with low concentrations of bisulfite to isolated leaves. The metabolism of the labeled amino acid will be examined by determining the distribution of label among various classes of compounds and within each class. These will be compared with control leaves to which bisulfite will not be given.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0312, BIOCHEMICAL EFFECTS OF SULFUR DIOXIDE ON HIGHER PLANTS
S.F. YANG, Univ. of California, School of Agriculture, *Davis, California* 95616

The present proposal is aimed at determining the biochemical mechanism by which SO sub 2 causes metabolic disturbance and tissue injury in plants and the biochemical mechanism by which plants may detoxify or tolerate the pollutant. The O sub 2 super minus and OH. radicals, which are generated during the aerobic oxidation of sulfite are particularly suspect as toxic agents. We shall examine the oxidation of certain biological molecules by this sulfite-oxygen system. Sulfite oxidase is suspected to be the key enzyme responsible for the detoxification of sulfur dioxide. The relationship between the relative sulfite oxidase activity and the relative plant susceptibility among various plants and plant parts will be examined. It is assumed that the inhibition of photosynthetic CO sub 2 fixation by SO sub 2 occurs through interaction of SO sub 2 with ribulose-1,5-diphosphate. We shall study this interaction using isolated chloroplasts and purified carboxydismutase. In addition, the possible mutagenic action of sulfite in plant tissues, the fate of SO sub 2 in plant tissues and a possible interaction of sulfite with certain coenzymes will be studied.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0313, EFFECT OF AIR POLLUTANTS ON TEXTILE FABRICS
S.H. ZERONIAN, Univ. of California, School of Agriculture, *Davis, California* 95616

To establish the effects of exposure to air pollutants, individually and in combination, on textile fabrics made from natural or man-made fibers.

To correlate these effects with variations in light, humidity and temperature.

To study the soiling and launderability of fabrics exposed to air pollutants.

To establish the limit placed on the useful life of textiles by air pollutants.

To explore potential methods for minimizing the undesirable effects of air pollutants on textile fabrics.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0314, VARIABLE TOXIC RESPONSE AS A MEANS OF OBTAINING SMOG-RESISTANT PLANTS
E.A. BALL, Univ. of California, School of Biological Sciences, *Irvine, California* 92664

Methods to obtain smog-resistant plants will be developed in two ways: (a) by the use of tissue cultures, and (b) by the use of soil- grown plants and the employment of established genetic procedures. Snapdragon plants, the test objects, will be grown in conditions of atmospheric pollutants, and those that show the minimum damage as judged by killed tissue, and inhibition of growth, will be used for inocula. Where possible, inocula will be taken immediately adjacent to lesions, thus starting with tissues having some resistance. Callus tissues will thus be estabished in vitro which have in their genes the desired characteristic of smog-resistance. After several growth periods in (1) pure air, or (2) polluted air, they will be used to regenerate whole plants. In the first case, it will be assumed that the original exposure to smog killed the susceptible tissues and left the resistant, which was later perpetuated. In the second, the repeated exposure to smog will restrict the growth to the most highly resistant tissue, and will also institute habituation of the tissues to grow in this unfavorable environment. Regeneration will be brought about, resulting in the formation of buds, shoots and roots; these plantlets will be transferred to soil where they will grow to maturity and sexual reproduction. In the second proposed method, snapdragon plants will be grown in smog, and those showing minimum lesions and inhibition of growth will be utilized as the seed-producers of the next crop. Recognizing that this selection by phenotype is not the best genetic practice, selection by genotype will also be instituted. Pure lines of plants will be obtained by continual self-pollination, and they will then be crossed, seeking in the hybrids the character of smog- resistance. Once establised in a hybrid line, procedures will be followed to produce seeds in commercial quantities. These standard genetic methods, especially the latter, will require a number of years to achieve results. In this exploratory research the ground-work will be established for future work.

1.0315, WIND TUNNEL INVESTIGATION OF MICROPHYSICAL PROCESSES IN SUPERCOOLED CLOUDS
H.R. PRUPPACHER, Univ. of California, Graduate School, *Los Angeles, California* 90024

The proposed research using the cloud tunnel and the Walk-in Chamber will include: (1) A determination of the freezing temperature and mode of freezing of water drops as a function of their size, purity and the purity of the air stream in which they are floating; (2) A determination of the activation energy for self diffusion of water molecules in supercooled liquid water; (3) A determination of the rate of evaporation of ice spheres and ice crystals of various shapes; (4) A theoretical study of the rate of mass transfer from a rigid sphere moving at its terminal velocity for Re 0's between 0.01 and 1000; (5) An investigation of the rate of growth from the vapor of an ice sphere and ice crystals of various shapes suspended on fine fibres in a saturated air stream; and (6) An investigation of the rate of growth of an ice sphere and ice crystals of various shapes, suspended on fine fibres, by collision with supercooled water drops and ice crystals.

In addition an investigation to determine the effect of man made pollutants on the ice formation in atmospheric clouds in the Los Angeles area will be continued.

SUPPORTED BY U.S. National Science Foundation

1.0316, STUDY OF EFFECT OF ATMOSPHERIC TURBIDITY ON SATELLITE SOUNDINGS
Z. SEKERA, Univ. of California, Inst. of Geophys. & Pla. Phys., *Los Angeles, California* 90024 (011751)

Conduct a research study to determine the effect of atmospheric turbidity on temperature and water vapor soundings from satellites.

(1) Investigate in detail the contribution of aerosol scattering in the infrared regions of interest for a particular aerosol model. Extend or modify the theories of radiative transfer to the case of internal sources to provide the theoretical relationship between the emerging radiation from an ideal atmosphere and from a turbid atmosphere with aerosol scattering. From this relationship attempt to derive the possible connections due to atmospheric turbidity to the measurements of temperatures and other atmospheric parameters. (2) Investigate in detail the polarization characteristics of the infrared radiation scattered by the aerosols for the particular model assumed and the feasibility of the determination of aerosol content from the polarization measurement in the infrared.

Progress: Numerical computation of the scattering source function has been more difficult than anticipated. These difficulties have now been largely resolved and the final computations can soon be made. Polarization properties have have not yet been considered, since they must be computed last. To complete this vital phase of the research, it is likely that an extension of the contract, with added funds, will be required. Preparation of a proposal is in progress.

1.0317, A BIOLOGIC INDICATOR FOR AIR POLLUTION
R.P. SHERWIN, Univ. of Southern California, School of Medicine, *Los Angeles, California* 90033

A recently developed biologic index for air pollution, based on the exposure of guinea pigs to low levels of NO2 (1$ ppm) and an increase in the number of alveolar wall cells (lactic acid dehydrogenase positive) per alveolus, will be applied in a series of experiments to determine the sensitivity, specificity, and time distribution of the test. Once reference baselines are established, the relative influence on the index of a variety of gases, singly and in combination, will be investigated. Data will be obtained in the important areas of a) minimum ambient levels of air pollutants (singly and in combination) that will produce an elevation in the response, b) synergism and antagonism of air pollutants, c) patterns of response according to the time and level of exposure, d) the role of suspended particles (carbon) as a vehicle for focal deposition of high levels of air pollutants, and e) variations of the index in five different ambient atmospheres (major cities and rural areas) over a period of 40 weeks. The study will ultimately be extended to comparisons of species differences and, in particular, the relationship of the index in human lungs (accidental deaths and operations) to major residential location, cigarette smoking, occupation, age, and sex.

1.0319, EFFECTS OF FLUORIDES IN AIR, WATER, AND SOIL ON GROWTH, QUALITY, AND YIELDS OF TREE, FIELD, AND VEGETABLE CROPS
R.F. BREWER, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-RO-SSE-1633-B)

OBJECTIVE: Determine effects of F accumulation on plant growth, crop yields and product quality. Determine interrelationships between F and other plant constituents such as Ca, P, Zn, Mn, and Al. Investigate the feasibility of protecting F-sensitive crops from F-polluted air by modification of cultural practices. Study the physical and chemical effects of F-containing irrigation waters on western soils.

APPROACH: Test plants will be exposed to known concentrations of HF in the air or will be sprayed with dilute NaF or HF sprays to study effects on growth, yields, fruit quality and nutrient content. Calcium sprays will be applied to greenhouse and field plants exposed to F to determine feasibility of obtaining protection. Western soils irrigated with F-containing waters will be examined for physical and chemical changes.

PROGRESS: The effects of fluoride accumulation during or after blossoming has been studied under field conditions using dilute HF sprays applied weekly to introduce the fluoride. Preliminary results of these studies indicate the fruit yields were depressed significantly by both the post and pre-fruit set applications, but the accumulation of F following fruit set had the greater effect. Fruit quality, particularly fruit size and taste, were also detrimentally influenced by the accumulation of fluoride after the fruit was set on the trees. Pine trees grown in soil to which various amounts of N, P, K, Mg and Ca were added were exposed to measured amounts of HF and SO(2) gases alone and in combination. Results indicate no synergistic effects of the combination of the two gases, but influences of the gases were strongly affected by the inorganic nutrient supply, particularly by nitrogen.

SUPPORTED BY California State Government - Sacramento

1.0320, EFFECTS OF DUSTS ON VEGETATION
E.F. DARLEY, Univ. of California, Air Pollution Research Center, *Riverside, California* 92507

This research project is a continuation of a study to determine the effects on vegetation of settleable industrial dusts. The primary emphasis at present is on dusts emitted from cement-kilns. Dusting experiments are conducted in special chambers wherein experimental dusts settle uniformly on plant leaves at rates of 0.5 to more than 3 grams per square meter per 8-hour dusting day. One set of chambers provides for short term experiments (2-3 days dusting) and a second set is used for long term experiments (up to 60 days) to provide for dusting to harvest stage of certain annual test plants. The factors of dust deposit being examined include particle size, chemical composition and degree of dust loading. Criteria for reponses of vegetation to various dusts include changes in apparent photosynthesis, visible injury, growth rate, and, where applicable, yield and quality of product.

1.0321, AIR POLLUTION EFFECTS ON AMINO ACID METABOLISM AND MEMBRANE PERMEABILITY IN CITRUS
H.E. HEGGESTAD, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (0000-05-02(C))

OBJECTIVE: Determine the effects of atmospheric oxidants on amino acid metabolism water status of leaf tissue, and water permeability of plant membranes.

APPROACH: Citrus and cotton varieties will be exposed to atmospheric oxidants, principally ozone, and free amino acids determined with an automatic amino acid analyzer during different stages of growth. The amino acid pool of resistant and susceptible varieties will be compared. Based on these analyses, chromatographic methods will be used to study amino acid metabolism using C labeled amino acid tissues. The relation to carboxylation of CO(2) will be studied in control and ozone

treated tissue. Beta ray gauging techniques and transpiration resistance will be used to measure the effects of oxidants on water status of leaf tissue, including solute permeability of membranes.

PROGRESS: Studies were conducted with Rough Lemon to ascertain whether or not it would be possible to obtain acute damage with concentrations of ozone in the one part per million range. Even after several hours of ozone treatment there was no visible injury to leaves of any age. Young citrus leaves responded to ozone treatment by an initial increase in the concentration of free pool amino acids just as shown with cotton. (See Accession No. 0019388.) Preliminary data suggest that aspartate, lysine, and ornithine increased. Certain protein amino acids, such as leucine, isoleucine, tyrosine, and methionine decreased. This evidence of altered metabolism in citrus plants, even though no visible injury occurred, reveals that ozone can cause some significant subtle changes detectable only by laboratory procedures.

SUPPORTED BY U.S. Dept. of Agriculture

1.0322, AIR POLLUTION EFFECTS ON AMINO ACID METABOLISM AND MEMBRANE PERMEABILITY - COTTON

H.E. HEGGESTAD, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (0000-05-02(C)A)

OBJECTIVE: See Accession No. 0019387.

APPROACH: See Accession No. 0019387.

PROGRESS: A diurnal variation in sensitivity of cotton leaves to ozone was found. The free pool amino acids were at a minimum during the beginning of a normal light period (morning) when the leaves are most sensitive to ozone. The concentration of soluble and reducing sugars also reaches a minimum at about the same time. The immediate effect of ozone treatment of cotton was a dramatic increase in the concentration of free pool amino acids which are normally associated with proteins. After several days, the concentration of free pool amino acids in ozone- treated leaves dropped below that of the control. The nonprotein amino acids seemed to decrease after exposure to ozone. These results indicate that the major effect of ozone relative to amino acid metabolism is a blockage of protein synthesis. (See also Accession No. 0019387.)

SUPPORTED BY U.S. Dept. of Agriculture

1.0323, EFFECT OF AIR POLLUTANTS AND OF OTHER ENVIRONMENTAL FACTORS ON PLANT CELL AND TISSUE GROWTH

L. ODRIN, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-SSE-2231)

OBJECTIVE: Determine effect of growth-inhibiting concentrations of air pollutants and of other factors on various biochemical reactions known or suspected to be involved in growth of plant cells. Specifically, determine effects on cell wall component synthesis and breakdown in various plant tissues; determine effects on enzymes involved in wall metabolism.

APPROACH: After exposure of intact plants or tissue sections to factors such as ozone, peroxyacetyl nitrate or nitrogen dioxide, growth will be determined. Comparison of net amounts of wall components formed with de novo synthesis by use of high concentrations of C -sugar will be made. Phosphoglucomutase, pyrophosphorylases and polymerizing enzymes will be assayed in homogenates and cell fractions from treated tissues.

PROGRESS: Lecithin micelles partially restored oat cellulose synthetase activity initially decreased by mild detergent treatment. Treatment of tobacco plants with peroxyacetyl nitrate at levels ultimately causing leaf necrosis, resulted in decreased leaf cellulose synthetase activity which was detected early. Uridine diphosphoglucose pyrophosphorylase activity increased, apparently due to release of enzyme from subcell particles, only after necrosis was observed. Indoleacetic acid-2-14C was administered to tobacco plants before and after exposure to peroxyacetyl nitrate. At least 6 indolic metabolites were produced in control and treated plants. One, reported in the literature as indolelactic acid, has been termed pseudo indolelactic because of different structure. There was an indication that hydroxymethyl oxindole also was produced in treated plants only. Labeling of uridine diphosphoglucose from glucose-14C in oat coleoptile sections was decreased by fluoride pretreatment of tissue; sucrose labeling was unaffected at lower fluoride levels. Labeling of nucleotide glucose, sucrose and cell wall from glucose-14C in coleoptiles was decreased by peroxyacetyl nitrate pretreatment of tissue yielding 50 percent growth inhibition (with auxin); at lower levels of oxidant, no effect on intermediate or sucrose labeling was noted except that glucose-14C-6 phosphate to glucose-14C-1 phosphate ratio increased slightly.

1.0324, INFLUENCE OF ENVIRONMENT, CHEMICAL ADDITIVES AND AIR POLLUTANTS ON APPARENT PHOTOSYNTHESIS AND RESPIRATION

O.C. TAYLOR, Univ. of California, Agricultural Experiment Sta., *Riverside, California* 92502 (CA-R0-PLS-2156-H)

OBJECTIVE: The objectives of the project are to study the effects of varied cultural practices, chemical additives, environment, and air pollutants on apparent photosynthesis and respiration by intact plant parts.

APPROACH: The CO(2) determinations will be made with appropriate infrared analyzers. The necessary equipment will be assembled to maintain the desired environmental conditions during the experiments. The most modern equipment available will be used to attain accurate measurements of the plant response to the varied treatments.

PROGRESS: Respiration (CO(2) release) increased sharply when tobacco callus tissue and small plants produced by tissue culture were exposed to ozone at concentrations up to 0.5 ppm. There was a lag of up to 30 minutes in respiration response time indicating that tissue injury preceded increased respiration. Ozone fumigations reduced the rate of photosynthesis but there was little, if any, measureable effect on CO(2) absorption when O(3) dosages were below the threshold required to produce visible injury. Ethylene is produced in automobile exhaust and by many industrial operations. Concentrations as high as 0.2 ppm are relatively common in ambient air. Extended exposure (5 to 10 days) to concentrations of about 0.5 ppm has produced excessive defoliation of many plants. One-hour exposures to high concentrations (5 ppm) caused no detectable defoliation, visible injury or change in CO(2) exchange. Eight-hour exposures of bean and tomato plants to concentrations of about 1.0 ppm ethylene caused significant reduction in photosynthesis and an increase in respiration. Emphasis is currently being placed on the identification of varieties of lettuce, tomato, radish, corn, barley and celery to ozone and PAN. Resistant varieties have been identified and will be used to determine effects of pollutants on photosynthesis and respiration.

SUPPORTED BY U.S. Dept. of Agriculture

1.0325, THE TOTAL EFFECT OF AIR POLLUTANTS ON BEARING CITRUS

C.R. THOMPSON, Univ. of California, Air Pollution Research Center, *Riverside, California* 92507

The broad objectives of this study are to extend the original project which was 'to determine under field conditions the effects of certain atmospheric phytotoxicants on agricultural crops grown in the upper Santa Ana Drainage Basin. The plan was to measure the effects of fluorides, ozone and other oxidants on plant growth, crop yield, longevity quality and keeping properties of fruits and other agricultural products.'

This will be done by extending and refining the present study of the effects of NO2 on navel orange trees so that the controlled exposure of the trees of this atmospheric toxicant is more in keeping with the varying diurnal levels which occur in the Los Angeles basin. Greenhouse and laboratory studies will be carried out to give basic biochemical information about the gross changes which are caused in the field by NO2.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0326, ENVIRONMENT - AIR POLLUTION INTERACTIONS ON PLANTS

D.P. ORMROD, Univ. of Guelph, *Guelph, Ontario, Canada*

1. AIR QUALITY

The overall objective is to precisely determine the relationship of the levels of environmental factors to the nature and severity of damage to plants by air pollutants. The effects of temperature, light intensity, atmospheric humidity and carbon dioxide levels before, during and after fumigation on responses to ozone and sulfur dioxide are currently being studied.

Several sensitive and tolerant plant species and cultivars are being evaluated. The results will be interpreted in relation to available data on outdoor weather conditions during plant damaging periods of air pollution.

The clarification of environment damage interactions will be followed by studies of the physiological and biochemical mode(s) of tolerance and susceptibility.

1.0328, ATMOSPHERIC TURBIDITY AND DIFFUSION

F.A. GIFFORD, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302 (001139)

Technical Objective: Study of the theory of the structure of energy transfer mechanisms of the planetary boundary layer. (This is a cooperative program with the Atomic Energy Commission and augments the larger programs sponsored by h m.)

Approach: Preparation of advanced mathematical models of the planetary boundary layer to analyze and predict wind and temperature profiles in adiabatic conditions. Incorporation, from first principles of energy transfer and radiation mechanisms that influence these profiles. The models will be tested via finite difference equation on high speed computers. A study of the changes in flow and energy transfers due to changes in surface roughness will be modelled and tested aginst existing observations, where available. Participation in advanced field programs to assist in their design to complement the model building will be carried out and data analysis from these programs will be a part of the overall research.

Prgress: Installation of an improved micro met system for two independent measures of energy dissipation was completed and initial field tests begun to verify the instrumentation and methodology. An approach to the planetary boundary layer problem through dimensional analysis and analysis of non-dimensionalized variables was undertaken. The results have led to the ability to formulte complete boundary layer models for testing. Considerable effort has gone into cooperative efforts with universities and state and local air pollution activities to transmit the accumulated information on the meteorological aspects of air pollution. A semester course was presented at Vanderbilt for scientists and engineers. An extensive series of seminars was presented at Syracuse.

1.0329, INADVERTENT MODIFICATION

UNKNOWN, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302 (001163)

Approach: The study of CO2 and O3 particulate matter and thermal radiation parameters will continue. New thermal radiation sensors, a new CO2 analyzer and automated recording equipment will be installed at MLO early in the fiscal year. The construction and instrumentation of a benchmark station on Niwot Ridge west of Boulder will be undertaken.

Progress: A detailed theoretical calculation of the depletion of available solar energy at the ground by solid atmospheric pollutants has shown that the initiation of climatic recession by such pollution is a distinct possibility.

1.0330, GEOCHEMICAL EXPLORATION TECHNIQUES IN ALPINE AND SUBALPINE ENVIRONMENTS

G.C. CURTIN, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

1.) To determine the physical and chemical factors that control the mobilization, transport, and deposition of metals in the zone of weathering in alpine and subalpine environments. 2.) To apply these factors to the development of favorable techniques in geochemical exploration for concealed ore deposits in alpine and subalpine environments. a) To evaluate the relative usefulness of sampling media, including rock, soil, humus, vegetation, stream sediment, and natural waters, for geochemical exploration in areas of varied geology and mineralogy, including areas of extensive surficial cover. 3. To evaluate, where applicable, the relationships between geochemical and geophysical data. 4. To develop criteria for determining the effects of surface contamination from mining, industry, automobiles, etc.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

1.0331, GEOCHEMICAL SURVEY OF THE VEGETATION OF MISSOURI

H.T. SHACKLETTE, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

States to which project pertains: Missouri.

The principal objective of this investigation is to describe the chemical character of the major vegetation types and the important native and cultivated plant species and associated soils within the State in order to determine if regional patterns in the abundance of certain elements exist. The characteristic element content of vegetation will be compared with that of soils on which the plants grow, and the contributions of vegetation to element cycling in the rock-soil- plant system will be appraised. Regional patterns of biogeochemical abundance, if found, will lend support to studies of geographical patterns of human and animal diseases that are being conducted by health agencies. Other objectives include (1) determining geochemical relationships within and between the major vegetation types, (2) characterizing the element content of native and cultivated plant species that are important in the food chain, (3) studying the predominant tendencies in element concentration by plant groups in order to determine at which level of the taxonomic hierarchy plants can be grouped to best represent chemical affinities, (4) documenting seasonal variation in element content of selected plant species, and (5) evaluating highway contamination effects on nearby plants.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

1.0332, EFFECTS OF PARTICULATES ON RADIOMETRIC MEASUREMENT OF SEA SURFACE TEMPERATURE & ON INFRARED COOLING RATES IN TROPOSPHERE (ABBREV)

W.E. MARLATT, Colorado State University, School of Engineering, *Fort Collins, Colorado* 80521

The objective of this research is the further analysis of data taken during BOMEX which includes radiation measurements and particulate measurements, together with data on the meteorological situation at the time of those measurements. The research will address the following questions: 1) The effect of atmospheric particulates on the radiometric sea surface temperature. 2) The effect of atmospheric particulates on infrared cooling rates and the earth's heat budget. 3) The variation of these effects with particulate size, concentration and type. Existing computer programs will be used to investigate these problems using BOMEX data.

SUPPORTED BY U.S. National Science Foundation

1.0333, NATURE AND CONTROL OF OZONE INJURY TO PLANTS
S. RICH, Conn. Agric. Expt. Station, *New Haven, Connecticut* 06504

The formation of toxic lipid compounds in ozonated leaves will be studied and related to subsequent development of visible ozone injury. Toxic lipids of leaves will be analyzed qualitatively and quantitatively by thin-layer and gas-liquid chromatography. Specific emphasis will be placed on esterified steryl glucosides (ESG) and lysolipids. ESG formation will be studied by addition of radioactive solutions of glucose and fatty acids and by sulfhydryl binding reagents which affect symptoms of injury similar to those of ozone. The possibility of an equivalent relationship between increased levels of ESG and lysolipids will be determined by comparative fatty acid analysis of ESG and hydrolysed phospholipids.

Qualitative and quantitative increases in toxic lipids will then be related to ozone-uptake and the extent of subsequent leaf injury. These studies will be conducted on leaves which give a very similar response to ozone and on leaves which give very different responses to ozone based on selective breeding and maturation. Knowledge gained from measured toxic production and related to natural inhibition and tolerance will be used to inhibit ozone injury in more sensitive plants.

Ozone uptake data will also be used to measure the ability of plants to purify an ozone contaminated atmosphere.

Electron micrographs will be made to compare the internal structure of ozone-resistant and susceptible varieties of plants.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0334, NATURE AND CONTROL OF OZONE INJURY TO PLANTS
H. TOMLINSON, Conn. Agric. Expt. Station, *New Haven, Connecticut* 06504 (CONH00393-AP)

Progress: Tobacco and bean leaves became more resistant to ozone when treated with emulsions of various lipids and fatty acids which did not occlude or modify stomata. Untreated tobacco leaves exposed to ozone lost 50% of their saturated fatty acids but only 10% of their unsaturated fatty acids. Fatty acid content could be correlated with ozone-resistance of untreated leaves only when genetically similar tobacco plants were compared. We compared the stomatal conductivity of different tobacco varieties and found that their susceptibility to ozone could be correlated with the stomatal conductivity of the under surface of the leaves. The faster the exchange of gases through the under surface, the greater the ozone damage. A technique was devised to mark those few cells killed when bean plants are exposed to barely toxic levels of ozone. After exposure to ozone, the plants were kept in the dark for 2 days during which time the starch grains disappeared from all the living cells but not from the killed cells. The killed cells could then be clearly marked by staining the leaf tissue with the starch stain, I-KI.

1.0335, INFLUENCE OF SELECTED AIR POLLUTANTS ON PHOTOSYNTHESIS OF MATURE FOREST TREES UNDER NATURAL CONDITIONS
D. BOTKIN, Yale University, Graduate School, *New Haven, Connecticut* 06520

This project will initiate a pilot study to determine levels of SO2 and O3 that produce observable changes in photosynthetic rate. The research will be conducted at Brookhaven National Laboratory using growth chambers and automatic digital recording systems available. If Threshold levels of pollutants that influence carbon dioxide flux are established successfully during the first year, a pilot field plot study will then be undertaken. White pine will be the initial plant to be examined because of its high sensitivity. Several technical problems must be resolved before field measurements are practical including precisely metered introduction of pollutants. However, the results of this project could have considerable importance for design of monitoring projects for atmospheric pollution.

SUPPORTED BY U.S. National Science Foundation

1.0336, LEAD AND SODIUM CONTAMINATION OF TREES AND SHRUBS IN URBAN ENVIRONMENTS
W.H. SMITH, Yale University, School of Forestry, *New Haven, Connecticut* 06520

The specific objectives of this investigation are several: 1. To determine the magnitude of lead and sodium contamination of selected tree and shrub species in New Haven and Hartford, Connecticut. 2. To ascertain the position of lead on or within contaminated plants. 3. To estimate the pathological significance of the lead and sodium contamination. 4. To make recommendations with respect to species selection for planting in certain environments within the city, and also with respect to appropriate planting distances from roads. 5. To gain a preliminary impression of the capacity of plants to remove particulate contaminants from the atmosphere. 6. To conduct a preliminary screening of selected plant tissues for possible industrial mercury contamination (Walton 1969) on selected sub-samples.

Cation content of sample tissues will be determined by atomic absorption spectrophotometry.

SUPPORTED BY Connecticut State Government

1.0337, OZONE DAMAGE TO PLANTS
S. RICH, Univ. of Connecticut, Agricultural Experiment Sta., *Storrs, Connecticut* 06268 (CONH00606)

OBJECTIVE: Determine conditions leading to ozone damage to plants; to observe which plants are damaged by ozone in Connecticut; and estimate extent of loss caused by ozone damage to plants. Find ways to protect plants from damage by ozone.

APPROACH: We monitor ozone in Connicticut air during summer months and relate ozone fluctuations to meteorological condition. We attempt to recognize and report instances of ozone damage to plants in Connecticut and estimate extent of loss. We search for plant varieties resistant to ozone, and for chemical treatments that would make plants more resistant to ozone.

PROGRESS: Periods during which concentrations of ozone were high enough to damage plants averaged once every 4 days during the 1963-1967 growing seasons in Connecticut. 80% of these periods occurred in the afternoon. Most lasted 1 to 6 hr. but a few lasted 7 to 9 hr. During the high-ozone periods the wind was usually from the southwest quadrant. There was no indication that pollution by ozone became progressively more severe during 1963-1967. During 1969, we exposed potato plants to ozone and produced symptoms identical to those we have seen on potatoes in the field. In July, 1969, necrotic blotches appeared on the foliage of Greening apples in many orchards in Connecticut. The leaves on the sunny side of the trees were most severely injured. We produced similar symptoms by fumigating branches with ozone, and suspect that the problem may be caused by air pollution. Tobacco plants treated with the systemic fungicide benomyl develop less fleck (ozone injury) than untreated plants. Dr. P.M. Miller reported that tobacco plants growing on soil previously treated with the nematicide Dasanit develop more fleck than plants growing on soil not so treated.

SUPPORTED BY Connecticut State Government

1.0338, AIR POLLUTION PROBLEMS IN THE NORTHEAST
D.J. FIELDHOUSE, Univ. of Delaware, Agricultural Experiment Sta., *Newark, Delaware* 19711 (DEL00125)

OBJECTIVE: Determine the impact of present air contaminants on the agriculture of the Northeast. Obtain information prerequisite for the development of air quality criteria as they relate to agriculture in the Northeast.

APPROACH: Research will deal with: establishment of the kinds of pollutants present, their concentration, their effects on plants and microorganisms in ambient air, and their relationship to local and area meteorological conditions; responses of plants and microorganisms to various concentrations and mixtures of pollutants in controlled environments; bioassay of pollutants by use of known indicator plants and a search for resistance/susceptibility in varieties, lines, and cultivars of various plant species and

in microorganisms; and the possible alleviation of damage to plants by selecting resistant lines, altering host nutrition, or the application of growth-regulating chemicals nd stomatal inhibitors.

PROGRESS: Total oxidant levels were recorded at two locations in Delaware during July and August of 1969. During this period, 5 pphm was the highest reading. This was lower than that recorded in 1968.//Tobacco plants (Bel-W3) were grown in Newark and Georgetown as indicator plants for recording oxidant damage. Damage was observed and recorded even though the oxidant readings were relatively low. Plant damage was also noted on beans and corn under field conditions.//Plants tested under growth chamber conditions for physical and chemical reduction in ozone damage have shown that Sunoco Folicote at a dilution of 1:25 to 1:100 and used as a spray or as a dip may be effective for reducing injury. This treatment showed very favorable results at ozone concentrations up to 20 pphm.//The plant growth regular succinic acid 2,2 dimethyl hydrazide (Alar) has been used on several species to reduce ozone injury. The short period required between application of the growth regulator and fumigation indicates that the material may be blocking entrance of the ozone rather than actually changing the susceptability of the tissue to injury.

SUPPORTED BY U.S. Dept. of Agriculture

1.0339, THE EFFECTS OF ATMOSPHERIC CONTAMINANTS ON THE DURABILITY OF BUILDING MATERIALS

UNKNOWN, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

During this period studies have been mainly concerned with measurement of the effects of ozone (at 1.5 ppm level) on the photo degradation of paints and plastics.

Weathering devices were modified to permit the introduction of gaseous air contaminants directly into the machine without polluting the room or building air supply. Experiments showed that levels of ozone and sulfur dioxide could be maintained within plus or minus 10% of their nominal values of 0.5 and 2.0 ppm, respectively.

When materials were exposed to continuous light in these devices at 0.5 ppm ozone level (85% R.H. and 90 degrees F), only vinyl and acrylic- latex paints were found to be slightly sensitive to ozone. If an intermittent light cycle with 100% R.H. during the dark cycle was used, ozone appeared to affect all paints and some plastics.

In a cooperative program with the Public Health Service, a first step was taken to establish relative levels of air contamination at the six NBS exposure sites. Air pollution 'effects packages' have been placed at the Gaithersburg and Ft. Holabird sites. These have been designated as stations 272 and 273 in the air surveillance network of National Air Pollution Control Administration.

SUPPORTED BY U.S. Dept. of Commerce - N.B.S.

1.0340, EFFECTS OF AIR-BORNE FLUORIDES ON CITRUS

C.D. LEONARD, Citrus Agricultural Expt. Sta., *Lake Alfred, Florida* 33850 (FLA-CS-01395)

OBJECTIVE: Determine the effects of air-borne fluorides on growth and yield of citrus trees under exposure to fluoride air-pollution. Determine the effects of fluoride compounds applied to citrus foliage. Survey groves to determine whether fluorine problem is diminishing or intensifying.

APPROACH: Five sites will be selected in the polluted area and one outside for establishment of 'giant pot' experiments. At each site, trenches 29' x 76' will be dug, and refilled with soil from one location for uniformity. Uniform trees will be planted in these 'giant pots' and observed 5 years for growth and yield under the air-pollution prevalent at each site. Air-borne fluoride content will be measured continuously. Randomized block experiments will be set up on 6 or more groves where air-borne fluorides are absent. Fluorides will be applied in aqueous sprays applied to the foliage. Several concentrations will be used. Leaf fluorine content, yield, and fruit quality will be determined. Leaves from approximately 30 selected groves will be sampled 2 to 4 times per year for 5 years to determine whether leaf fluorine levels are becoming higher or lower in the area being studied.

PROGRESS: Some significant reductions in the 1969-70 crop yield were obtained from young orange, grapefruit, tangelo and tangerine trees set in 1967 in 'giant pots' measuring 76 by 29 feet at locations exposed to varying concentrations of air-borne fluorides (F). The average concentrations of F in the air during the bloom period from Feb. 24 to April 27, 1969, varied from 0.03 (control) to 0.38 parts per billion (PPB). The 1969 spring flush leaves from different varieties ranged from 1.0 to 42 PPB F when sampled in May, and from 1.1 to 138 PPB F when sampled in late September, 1969. There was little difference in trunk growth of the trees. Hydrofluoric acid (HF) spray experiments started in bearing citrus groves in 1967 were continued in 1968 and 1969. The 4 different HF concentrations of the sprays applied in 1968 varied from 0.005 to 0.016 normal. Some significant differences in yield and internal quality of fruit were obtained from the HF-sprayed trees as compared with the checks for the 1968-69 crop. These differences varied with variety. Some significant differences in yield and internal qua (Text Truncated - Exceeds Capacity)

1.0341, EFFECTS OF AIR-BORNE FLUORIDES ON CITRUS

C.D. LEONARD, Univ. of Florida, Agricultural Experiment Sta., *Lake Alfred, Florida*

Two major experiments are being conducted. One of these involves growing young citrus trees in identical 'giant pots' measuring 76 x 29 feet. The trees were set in the pots in August, 1967. Five such pots are distributed within the area affected by air-borne fluorides emanating from phosphate manufacturing plants. Two more pots are located at the Citrus Experiment Station near Lake Alfred, Florida, which is exposed to very low levels of air-borne fluorides. One of the Station pots is designated as the check and the other is being used to apply dilute hydrofluoric acid sprays to build up different levels of fluorine in the leaves. The effects of different levels of fluorine in the leaves on tree growth and yield of fruit is being studied. Continuous air-sampling for fluoride content is being carried on at each giant pot site.

The other experiment involves application of dilute hydrofluoric acid sprays to commercial bearing citrus groves far removed from the area affected by air-borne fluorides. Four different concentrations of dilute hydrofluoric acid are being applied at different times of the year to study the effect of different leaf fluorine levels on yield and quality of fruit. Three orange varieties and one grapefruit variety are included in this test.

1.0342, ATMOSPHERIC OZONE AND WEATHER FLECK ON FLORIDA CIGAR-WRAPPER TOBACCO

C.E. DEAN, North Fla. Agric. Expt. Sta., *Quincy, Florida* 32351 (FLA-NF-01380)

OBJECTIVE: Study ozone-induced fleck and the reaction of varieties to abnormally high ozone concentrations. Study meteorological conditions which contribute to abnormally high concentrations of ozone and correlate fleck with ozone concentrations. Develop a procedure for predicting increases in ozone concentrations and fleck occurrences on Florida wrapper tobacco.

APPROACH: An electrochemical ozone sensor will be used to continuously record concentrations of ozone. Test plants will be grown to correlate leaf damage with ozone. Meteorological phenomena occurring before, during and after increases in ozone concentrations will be recorded and analyzed.

PROGRESS: Two Mast ozone recorders were operated continuously during the 1969 tobacco crop season. Ozone concentrations exceeded 4 pphm 15 times in May, 9 times in June, 3 times in July. Four parts of ozone per hundred millions parts of air is the threshold value at which susceptible varieties of tobacco will fleck under high soil moisture conditions. The highest concentration recorded during the crop season was 7 pphm on June 10. Rises were always associated with hazy conditions substantiating the observations of previous years that ozone is photochemically produced from air pollution near the surface. Increases above 4 pphm were also associated with continental polar air masses that covered the southeastern part of the country. Small increases in

ozone concentration were associated with some, but not all thunderstorms. Fleck damage was minimal considering the number of times ozone reached critical levels. Only the most susceptible varieties were damaged. Extreme drought conditions along with high daily water demand by the plants accounted for lack of fleck.

SUPPORTED BY Florida State Government - Tallahassee

1.0343, EFFECT OF FLUORIDE ON PLANTS

A.C. WIESE, Univ. of Idaho, Agricultural Experiment Sta., *Moscow, Idaho* 83843 (IDA00293)

OBJECTIVE: Determine if there are important differences in the metabolic pathways of plant species which are susceptible or resistant to fluoride and investigate the nature of fluoride compounds in plants.

APPROACH: Gladiolus and alfalfa plants, representing susceptible and resistant species will be used. The effect of fluoride on enzyme systems obtained from these plants will be compared. The first enzyme will be phosphoglucomutase. Localize the effect of fluoride on enzyme systems to determine whether this is the cause of fluoride sensitivity. The enzyme studies will be correlated with other studies to determine how certain plant species accumulate abnormally high amounts of fluoride.

PROGRESS: Phosphoglucomutase (PGM) is inhibited by fluorine ion; 24 mumols causes 90 to 100% inhibition. Incubating the enzyme with histidine and Mg of activity. Enzyme preactivation was inhibited by F and F added after preactivation was equally inhibitory. Using specific ion electrodes it was found that the substrate glucose-1-phosphate (G-1-P) bound Mg ion, but that G-1-P did not bind F ion. Evidence was obtained for the formation of such complexes as MgF ion, (G-1-P)-MgF or PGM-MgF . The inhibition of PGM by F is probably due to the formation of one of these complexes.

1.0344, METEOROLOGICAL CONSEQUENCES OF THERMAL POLLUTION

J.E. CARSON, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

The objective of the study is to determine how the atmosphere will react quantitatively to the large amounts of heat energy and water vapor it will be forced to accept as a result of waste heat from nuclear power plants around the south rim of Lake Michigan. Nuclear plants with a capacity of 7000 MWe are being installed; most of the reject heat energy will enter the atmosphere as a result of evaporation, conduction, and radiation. The meteorological consequences of alternate heat sinks (cooling ponds and cooling towers) will be investigated.

To date, no evidence of weather or climatatic changes due to once- through cooling of power plants using water from a large, deep lake, such as Lake Michigan has been found. Meteorological equipment will be placed near the outfall on an existing 1100 MWE power plant and at a similar site far from any outfall. Climatological data will be examined for long-term temperature and snowfall trends. A program to measure fluxes of heat and water vapor over thermal plumes is being considered.

Results: This was a new project in FY 1970. Calculations show that the amount of nuclear energy added to the lake is extremely small compared to the imput via solar radiation; the heat added to the lake by the nuclear power plants during one year (assuming that they operated at 100% capacity for the entire period) is equivalent to the solar energy received at the lake in 2 hours in June. Observations at existing thermal plume sites show no significant (measureable) weather changes. Observations show that Lake Michigan has cooled by 2 degrees F in the past 40 years despite being used as a thermal sink by industry.

1.0345, ATMOSPHERIC CONSTITUENTS OF THE TERRESTRIAL-TYPE PLANETS

L.C. MARSHALL, Southern Illinois University, Graduate School, *Carbondale, Illinois* 62901

The purpose of this work is to investigate the formation of constituents that comprise the atmosphere of terrestrial planets such as Earth, Mars, and Venus. This is a continuation of work that began under the direction of Drs. Lloyd Berkner and Lauriston Marshall. The continuing research will include the following areas: (1) further study of 02 stability in the earth's atmosphere using an E2 Oxygen Analyzer and the differential photometric technique; (2) measurements of atmospheric constituents using remote sensing methods such as lasers; (3) studies of the effect of oxygen deprivation on several pure strains of blue-green algae; (4) the effect of pollutants and pesticides on blue-green algae and other oxygen producing organisms; (5) the effect of high magnetic fields on blue-green algae and the chemicals that are important to their composition and functions; (6) studies of crystalline materials and molecular structures of biological systems at the molecular level; and (7) studies of the mechanisms of cyclic and noncyclic photosynthetic photophosphorylation.

1.0346, EFFECT OF ATMOSPHERIC POLLUTION ON PRECIPITATION

S.A. CHANGNON, State Water Survey, *Urbana, Illinois* 61801

A review of research concerning urban-industrial effects on precipitation in the United States was made, and further research concerning urban effects on thunderstorms in the St. Louis and Chicago areas was performed. The general results showed that urban-industrial areas in the central United States produce increases in rainfall, thunderstorms, and hail that are 5 to 30 percent greater than that occurring in the unaffected rural areas. This research is continuing.

SUPPORTED BY Illinois State Government - Springfield

1.0347, CLIMATOLOGICAL ASSESSMENT OF URBAN EFFECTS ON PRECIPITATION

F.A. HUFF, Univ. of Illinois, State Water Survey Division, *Urbana, Illinois* 61802

This project is a two year study to obtain climatological information for eight specific urban locations in an attempt to assess the effects of urban sizes, industrial complexes, pollutants and thermal outputs upon the precipitation patterns of the city and its local sphere of influence. Historical climatological records will be examined to determine the existance of urban effects on precipitation, the likely causes of any detectable changes, and the differences in changes attributed to cities with a variety of industrial activity, physical size, population, and geographical location. It is expected that the effects of inadvertant weather modification by urban environments may have a greater bearing on local climatic changes than many of the intentional weather modification program now being contemplated for implementation.

1.0348, INTERDISCIPLINARY STUDIES - QUANTUM ELECTRONICS IN LIFE SCIENCES

H. MERKELO, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

Techniques developed in quantum electronics for studying very fast processes in luminescent systems are applied to a study of the dynamics of inductive energy transfers in living cells. Such nonradiative migration of excitation-energy is, possibly, the most important and, certainly, the fastest reactions (10 to minus the 12th power sec) of the photosynthetic apparatus. Emphasis is placed on determining the rates of homogeneous and heterogeneuos inductive transfers, both in vivo and in vitro, and on establishing the effects of industrial by-products on the efficiency of the photosynthetic apparatus.

1.0349, EFFECTS OF CIGARETTE SMOKE ON PLANT CELLS IN TISSUE CULTURES

P.S. SABHARWAL, Univ. of Kentucky, Agricultural Experiment Sta., *Lexington, Kentucky* 40506 (E5-3-72(C))

1. AIR QUALITY

OBJECTIVE: Develop a new bioassay method based on the effects of cigarette smoke on plant cells in tissue cultures.

APPROACH: Plant tissue cultures of Lemna gibba, Allium cepa, hybrid tobacco (Nicotiana langsdorffia X N. glauca), and callus tissue of Nicotiana tabacum will be maintained. These plant materials will be exposed to the following: standard puffs of tobacco smoke from the University of Kentucky smoking machine, smoke fractions at varying concentrations, and known amounts of individual smoke components such as dimethylnitrosamine, benz(a)anthracene, and methyl benzo(a)pyrene. Cell growth responses will be determined and documented photographically. Morphological, growth physiological, cytological and/or biochemical responses will be determined by comparison with suitable controls. Applicability of the test results to the development of a new bioassay method for cigarette smoke, and fractions thereof, will be appraised.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

1.0350, ENVIRONMENTAL REQUIREMENTS OF POULTRY

R.B. WILLIAMS, Univ. of Maine, Agricultural Experiment S *Orono, Maine* 04473 (ME00182)

OBJECTIVE: Determine the physiological responses of chickens to variations in light, dust and thermal environment.

APPROACH: Birds grown in a dust free environment will be exposed to sterile poultry house dusts and similar dusts innoculated with known microbial concentrations. Bird response will be determined by various physiological measurements. Determine feasible means for controlling harmful dust at a safe level.

PROGRESS: The dust insult chambers have been modified to allow insertion of only the bird's head; therefore the bird's body remains accessible for monitoring and sampling. Several types of dust sampling and estimating apparatus have been constructed which might be used in the field. Two different methods of microbial quantitation were successfully used in the laboratory: (1) Forced impingement on a nutritive coated plate (2) Chemical luminescence. Alteration of some hematologic areas were found during dust insult. Liquid crystals were not found to be a practical remote bird temperature sensing device. Electrocardiographic records have been made on several chickens of different ages before, during, and after dust insult. Results vary with technique and lead position but indicate that some pattern differences exist due to dust as a stress. Further refinement of technique is necessary.

SUPPORTED BY U.S. Dept. of Agriculture

1.0351, ACTION OF AIR POLLUTANTS ON PLANTS AND METHODS OF DAMAGE CONTROL ESPECIALLY THROUGH RESISTANCE

H.E. HEGGESTAD, U.S. Dept. of Agriculture, Plant Air Pollution Laboratory, *Beltsville, Maryland* 20705 (0000-05-01)

OBJECTIVE: Basic research directed toward better understanding of how air pollutants act on agronomic, horticultural and ornamental plants, and the development of methods for controlling air pollution damage including resistant varieties.

APPROACH: A wide spectrum of plants will be subjected to pollutants in ambient air and to one or more photochemical air pollutants under controlled conditions, differences in response will be studied and the physiological, morphological and biochemical basis of the effect established.

PROGRESS: Determined effects of photochemical oxidants on growth and yield of 8 potato (Solanun tuberosum) varieties. Plants were grown in a greenhouse supplied with air filtered through activated carbon to remove oxidants and in an adjacent greenhouse with ambient air. Haig and Norland had the most leaf injury. Tuber yields of Haig, Irish Cobbler, and Norland were about 50% lower in the ambient air. Yields of Avon, Superior, and Peconic were reduced 11, 20, and 24% respectively. Kennebec and Alamo produced about the same yield in both environments. Phenolic composition was significantly altered in Tempo bean leaves cultured in polluted ambient air. Fluorescent compounds were concentrated in the reddish-brown leaves. The level of caffeic acid in injured leaves was twice that detected in healthy leaves. Although anthocyanin is formed in leaves of Rumex Crispus after exposure to smog and ozone, it was not detected in the injured bean leaves. Discovered that mechanical wounding of the beans resulted in galls on plant parts. The response of major sites (chloroplast and cytoplasmic ribosomes) of protein synthesis to ozone were investigated with Pinto bean. Chloroplast polysome level was reduced more than the cytoplasmic polysome. RNA components of chloroplast ribosomes decreased more than those of cytoplasmic ribosomes. Results indicate that protein- synthesizing capacity is impaired by ozone.

SUPPORTED BY U.S. Dept. of Agriculture

1.0352, LITERATURE REVIEW ON THE EFFECT OF AIR POLLUTANTS ON LIVESTOCK AND POULTRY

R.J. LILLIE, U.S. Dept. of Agriculture, Animal Science Research Div., *Beltsville, Maryland* 20705 (032909390121)

OBJECTIVE: Conduct an exhaustive research, summarize and interpret the literature on air pollutants.

APPROACH: Conduct a comprehensive literature search and review of published information on the effects of air pollutants on livestock and poultry. It will include all experiments in which any of the pollutants were used or studied. The information will be compiled by chemical compounds, by class of livestock and poultry and by the type of physiological or pathological effect. Potential benefits from further experimentation will be described and evaluated.

PROGRESS: The literature review on the effect of air pollution on livestock and poultry which involved 1200 papers was completed. This review indicates that fluorides, arsenic and lead appear to be the most critical air pollutants for domestic animals. The rank of decreasing susceptibility among farm animals was demonstrated for cattle, sheep, horses, swine, rabbits and poultry exposed to fluorosis, but not clearly demonstrated for all classes of farm animals exposed to other air pollutants. Although not directly compared to other farm animals, the honey bee, which is valuable as a crop pollinator and as a producer of honey, appears to be more susceptible than cattle to fluoride and arsenic. If early stages of atmospheric poisoning are detected among farm animals, the animals can be salvaged for continued production of eggs, milk, meat and wool, provided these animals are protected from further atmospheric pollution. Although the fluoride content of milk from poisoned cattle has never been found to exceed the safe limit for humans, the calcium content of milk has been found to exceed this limit in several cases.

SUPPORTED BY U.S. Dept. of Agriculture

1.0353, BREEDING, GENETICS AND DISEASE CONTROL OF ALL TOBACCO TYPES

H.A. MENSER, U.S. Dept. of Agriculture, Crops Research Division, *Beltsville, Maryland* 20705 (0500-03-01)

OBJECTIVE: Develop varieties and breeding material of all tobacco types with resistance to diseases (pathogenic and physiological) and varying levels of chemical constituents. Transfer of disease resistance factors from Nicotiana species and foreign tobacco introductions into usable breeding material. Obtain information on air pollutants, and the physiology and anatomy of pathogens.

APPROACH: Conduct comprehensive breeding and genetics program including evaluation of germ plasm, transfer of desirable characters to all tobacco types for disease resistance, varying chemical constituents, and other economic characters. Conduct studies on the physiology and anatomy of plant pathogens and their affect on resistant and susceptible tobaccos. Study the effect of air pollution on tobacco and develop methods of control. Field evaluation of new Maryland type breeding lines at Upper Marlboro, Maryland for local adaptations is conducted as a satellite of the investigations.

PROGRESS: Optimum postinoculation temperature for infection by A. tenuis (brown spot) is 20 C. Other requirements for successful inoculation are moisture on the leaves for 3 days, pathogenic isolates and a concentration of 30,000 conidia/ml. This information makes possible greenhouse testing for resistance. Most of the chlorotic area surrounding brown spot lesion is free of fungal invasion, therefore, pathogenesis involves production of a halo inducing factor. Some of the chemical

characteristics of this factor are: stability to autoclaving for 15 minutes at 15 psi; solubility in acetone, ethanol and water; insolubility in ether; slight solubility in chloroform; not precipitated by (NH(4))(2) SO(4) or phosphotungstic acid, and stability to heating with concentrated acid. TI 1466 was found to be resistant to blue mold and is being used in crosses to develop blue mold resistant tobacco. The resistance in the line is from N. excelsior. In studying plants subjected to air pollution sensitivity, those under water stress were more resistant to ozone than plants watered normally. Nine burley varieties were tested for susceptibility to air pollutants. In the field Bu 49 and Ky 12 showed the greatest tolerance.

1.0354, CLIMATIC CHANGES THROUGH URBANIZATION

H.E. LANDSBERG, Univ. of Maryland, School of Engineering, *College Park, Maryland*

For the past three years micro - and meso-meteorological studies have been carried out in Howard County, Maryland, where the new town of Columbia is converting a rural area into an urbanized community. During the growth from a few hundred to ten thousand inhabitants measurable atmospheric changes have occurred and been documented.

Further growth of the town to 100,000 persons is expected. It is proposed to continue this study with special emphasis on the following points: (1) Pursue to study of heat island, including the radiation balance and attempt to measure the development of the country breeze. (2) Make a quantitative assessment of stream run-off in the urbanized area during heavy rainfalls. (3) Begin systematic observations of turbidity and compare values obtained with similar data from the Washington-Baltimore area. Make more sophisticated air pollution measurements in the area than heretofore. Include 'noise' in the pollution monitoring program and relate it to meteorological conditions. (4) Compare changes in meteorological data with those neighboring stations in undisturbed environments. Make meso-synoptic study to see if the town already creates an influence on showers. (5) Prepare an outline of possible remedies to counteract adverse meso-meteorological changes in town areas for consideration in planning of future new towns.

1.0356, LOPHODERMIUM NEEDLE CAST DISEASE AND OZONE DAMAGE ON WHITE PINES

W.M. BANFIELD, Univ. of Massachusetts, Agricultural Experiment Sta., *Amherst, Massachusetts* 01002 (MAS00298)

OBJECTIVE: Identify and appraise the comparative pathology and damage induced by ozone and Lophodermium pinastri Chev., operating either sequentially or concurrently.

APPROACH: Comparison of the disease syndromes induced on susceptible white pines by exposure to Lophodermium, ozone, or both concurrently or sequentially on greenhouse plants otherwise shielded. Identification of the complicity of these agencies in the genesis of the white pine blight complex of field trees by cultural studies of affected foliage and by exposure of this foliage to disease inducing thresholds of ozone. Appraisal of the comparative damage of these two agencies to white pine in New England. Identification of practical techniques for their control.

PROGRESS: Diseased plants selected in the nursery were grown for two years behind activated charcoal filters during which time they developed an entirely normal dark green foliage. Of 47 such plants exposed for up to thirty 12 hour periods of fumigation with 0(3) at 5 pphm, multiple spotting of their needles was induced on only two. Fifty-two of 54 plants fumigated with SO(2) at 100 5 pphm for up to 42 consecutive 12 hour daylight periods remained dark green and spotless. Numerous stomatal line spots developed on the new foliage of the other two. All 68 plants exposed to a mixture of 0(3) and SO(2) both at 5 pphm, mostly developed a sickly yellow green color, lost all their one and two-year needles, and developed a profuse spotting of new needles, accompanied by variable quantities of blight (death and red orange discoloration of needle ends). When such exposures were made at saturated humidity, these disease symptoms were initiated even from one 12 hour exposure to SO(2) at 2.5 pphm and O(3) at 10 pphm. Results indicate the disease is due primarily to the combined action of ozone and sulfur dioxide, and that intensity of disease response is conditioned by relative humidity and length of exposure.

1.0357, AIR POLLUTION PROBLEMS IN THE NORTHEAST

W.A. FEDER, Univ. of Massachusetts, Agricultural Experiment Sta., *Amherst, Massachusetts* 01002 (MAS00272)

OBJECTIVE: Determine the impact of present air contaminants on the agriculture of the Northeast. Obtain information prerequisite for the development of air quality criteria as they relate to agriculture in the Northeast. The first objective will be met by the implementation of a comprehensive regional survey. The second objective will be met in a number of program areas which are described below.

APPROACH: Relate plant injury from phytotoxicants to regional meteorological conditions, and determine responses of plants to different air pollutants. Massachusetts will contribute to this program area by comparing growth rate, quality, yield, and the characterization and symptomalogy of specific responses of commercial greenhouse crops.

PROGRESS: Growth and development of Olympic Red cultivar of geranium growing in 100 cubic foot Mylar chambers supplied with 10 pphm of ozone for 9 hours per day for three months was compared with plants of the same cultivar growing in identical chambers but receiving only ozone-free air. Ozone was supplied only during daylight hours. Plants in ozonated air developed fewer, smaller leaves, longer internodes, and about 30% fewer side branches than those growing in ozone-free air. The leaves are chlorotic and exhibited marginal flecking and premature senescence and abscission. Flower quality was unaffected but flower shelf life was markedly shortened. The number of blossoms per branch was unchanged but the reduction in number of side branches reduced the total number of flowers produced by about 50% in ozonated air. Growth in ozonated air resulted in a taller, thinner, yellower plant with fewer flowers. Monitoring of ozone and oxides of nitrogen in suburban Boston revealed that levels of these pollutants at least equalled those found in downtown areas of Washington, Cincinnati, and San Francisco. Sulfur oxide levels showed a sharp rise during summer 1969.

SUPPORTED BY U.S. Dept. of Agriculture

1.0358, CLOUD EFFECTS ON PASSIVE MILLIMETER WAVE RADIOMETRIC TEMPERATURES

W.H. BAUCOM, Sperry Rand Corporation, *Sudbury, Massachusetts* (000644)

Technical Objective: To determine the microwave remote sensing technique's altitude capability and its sensitivity to adverse weather conditions.

Approach: Conduct an analytical and experimental study to isolate the effects due to clouds, instrumental effects, and mode of operation on the measured brightness temperature; the results will establish the influence of clouds on radiometric observations of the atmosphere at altitudes up to 25,000 feet. For the analytical phase, computer simulation studies will be conducted to establish the characteristics of the equipment, mode of operation, and data reduction techniques that must be implemented in the experimental program. Then, the experimental studies of cloud effects will be conducted using a 50 to 60 GHz Radiometer.

1. AIR QUALITY

Progress: During August and September 1969, computer simulation of the microwave technique indicated that infomation from as high as 30,000 feet can be received at the ground if the operating frequency is 53.5 GHz. In the experimental area simultaneous radiometer and radiosonde runs were made on three days during which the sky was clear but when air pollution conditions were quite different. Other radiometer measurements for cloud and no-cloud conditions were made. Preliminary indications are that pollution and middle clouds have little effect on the brightness temperature measured by the radiometer at these frequencies. On the other hand, it appears that a cumulus congestus on the verge of precipitation does significantly change this temperature.

SUPPORTED BY U.S. Dept. of Commerce - E.S.S.A.

1.0359, THE ULTRASTRUCTURE OF NORTH AMERICAN HEPPIACEAE

C.M. WETMORE, Univ. of Minnesota, Graduate School, *Minneapolis, Minnesota* 55455

Lichens are one of the most sensitive indicators of air pollution because they are composed of algae and a fungus in a symbiotic relationship. They are also very sensitive indicators of climate. A better understanding of the lichens and the nature of the symbiosis would be beneficial to their utilization as indicators in ecological studies.

This research involves the comparative study of the ultrastructure of all of the 16 taxa in the lichen family Heppiaceae in North America. Using the electron microscope, a comparison will be made between the isolated algae and fungi and the intact lichen. The organelles unique to lichens will be further investigated in an attempt to determine their function in the lichen. By studying the ultrastructural differences in the same species in different ecological conditions and in different environments, information can be gained which will be useful in quantifying damage due to environmental changes. The principal objective is to expand knowledge of evolutionary relationships of this recently monographed group by including ultrastructural data.

The results should also stimulate further work on the ultrastructure of lichens by improving techniques used in working with lichen. It should also aid in understanding the unique cellular organelles and the nature of the lichen symbiosis.

SUPPORTED BY U.S. National Science Foundation

1.0360, INVESTIGATIONS IN THE THERAPY OF BOVINE LEAD POISONING

P.B. HAMMOND, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-26-026)

OBJECTIVE: Study of lead-mobilizing characteristics of chelating agents; investigate the lead content of vegetation as related to distance from roadways having variable traffic densities. Analytical data will be gathered once again with special attention to certain procedural details which may account for the disparity between our results and those of others.

APPROACH: Various analytical methods are being used to determine lead content in specimens from animals and plants. EDTA will be used to treat lead poisoning and to study the mode of action of chelating agents.

PROGRESS: The major effort during the past year has been devoted to defining the kinetics and compartmentalization of lead in the body. We had hoped to use the Armac whole body counter in connection with these studies. Problems relating to the design of the instrument have not as yet made this possible. Nevertheless, certain results of importance have emerged. The whole body burden of lead over 37 days following intravenous administration decreases at a rate which can be described by a single first order rate constant from day 4 to day 37. From day 10 to day 37 the skeletal burden falls at the same rate as the whole body burden. As a corollary of the above, the soft tissue burden falls at the same rate as the whole body burden. It had been anticipated that it would fall considerably faster. Also, the exchangeable fraction of bone, defined by the amount of lead mobilized from bone by a standard dose of EDTA, decreases considerably faster than the whole body burden or the total skeletal burden. This finding had been anticipated. Other results obtained during the year indicate that doubling the dose of EDTA by doubling the duration of the infusion period substantially increases the fraction of metal removed from bone and, to a lesser extent, from soft tissue. Also, we have determined that the chelating effects of EDTA are similar regardless of whether one is dealing with carrier or tracer doses of lead.

1.0361, EFFECTS OF AUTO EXHAUST ON ROADSIDE MAMMAL POPULATIONS

J.L. WOLFE, Mississippi St. University, School of Arts, *State College, Mississippi* 39762

Previous work on the effects of motor vehicle emissions on mammals has consisted primarily of laboratory studies in which test animals were subjected to high concentrations of auto exhaust for relatively short periods. I propose to take this work into the field and compare several physiological, behavioral, and ecological parameters of cotton rats, 'Sigmodon hispidus', living in areas of high contamination (on road shoulders) and in uncontaminated areas. More specifically, heart rate, blood pressure, EKG, breathing rate, hematocrits, blood cell counts, adrenal and spleen weights, condition of lungs and liver, reproduction in the field, movements and spatial relationships of individuals in the field, population density and structure, exploratory behavior and spontaneous activity, social interactions, feeding behavior and weight changes, and carboxyhemoglobin and lead levels in the blood will be investigated.

Organic and inorganic particulate materials undoubtedly reach high concentrations along highway rights-of-way. Although toxic gases probably never reach the concentrations utilized in laboratory tests, animals inhabiting road shoulders are exposed continually, which could have an effect over a period of several months. Small mammals of this type occupy definite home ranges which would tend to keep individuals occupying road shoulders in constant direct contact with contamination.

Since several aspects of the animals' ecology and reproduction under natural conditions are included, the study could provide information on long range population effects of contamination, as well as on direct effects on individual animals.

1.0362, ATMOSPHERIC IONS AND THE INFECTION PROCESS OF FUNGI

E.L. SHARP, Montana State University, School of Letters, *Bozeman, Montana* 59715

An investigation will be made on the influence of naturally occurring atmospheric ions and associated particles on the infection process of a plant pathogenic fungus. Three separate phases of the infection process - germination, penetration and symptom development - will be investigated. Attempts will be made to determine if specific air ion mobility groups are stimulatory or inhibitory to the various phases of the infection process. The influence of various sized uncharged particles will also be investigated. Experiments will be designed to test the relative efficacy of the positive and negative ions. The effects of various sized generated inert particles on the small ion content will be related to development of the different phases in the infection process. A number of meteorological factors will be monitored to determine their relation to the air ion mobility spectrum and particulate matter in the air. The meteorological data will also be evaluated in relation to development of the infection process during coinciding periods.

1.0364, A STUDY OF PLANTS GROWING IN POLLUTED ATMOSPHERES

C.C. GORDON, Univ. of Montana, School of Arts, *Missoula, Montana* 59801

This research program is designed to obtained further knowledge of the effects of various toxic gases on the tissues of selected species of Gymnosperms and Angiosperms. This will be accomplished by: 1. continuing to investigate the specific disease syndromes manifested by the tissues of plants growing in areas where toxic gases are present in the ambient air; 2. growing plants under controlled conditions in known concentrations of toxic gases to ascertain if histological and cytological responses to pollutants occurring in the field can be duplicated in the laboratory; 3. obtaining chemical analysis of cultivated and native vegetation from polluted areas of Montana and from controlled fumigation studies; and 4. Carrying out atmosphere gas analyses in polluted areas.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.P.P.

1.0365, PHYSIOLOGICAL RESPONSES OF PLANTS TO TOXIC AIR POLLUTANTS

E.G. BRENNAN, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00390)

OBJECTIVE: Investigation of the role of plant nutrients and other metabolites on the reaction of plant tissues to air pollutants. Investigation of the effect of air pollutants on plant metabolism at the cellular and subcellular level by studies of respiration, enzyme systems, host-parasite relationships, and other metabolic systems.

APPROACH: Plants sensitive to each pollutant will be grown in sand culture with a deficient, optimum, and luxury supply of various nutrients, exposed to the pollutant, harvested at various stages and analyzed for the nutrient involved. Respiration rates, nitrogen fractions, carbohydrate constituents and A T P production will also be determined. Species sensitive to a particular pollutant will be grown in sand culture and then exposed to the pollutant. The chloroplasts and other organelles will be separated by centrifugation. Respiration rates will be measured at the cellular and subcellural level with a Warburg manimetricon. Oxidation-reduction potential will be measured by methods, yet not to be investigated. If an electron microscope is available, the effect of the pollutant on the ultrastructure of the organelles will be determined.

PROGRESS: Local lesion assays of TMV-infected N. sylvestris showed more virus activity in ozonated than in control plants. Bean plants ozonated 3 or 24 hrs. after inoculation with TMV had more lesions than control plants./ Low 0(3) exposure increased the permeability of Bel W-3, but not of Bel B; a high exposure increased Bel W-3 permeability more than Bel B. Tomato and tobacco plants grown with high calcium showed enhanced 0(3)-sensitivity./ In solution culture tomato plants ozone injury increased with increase in phosphorus level./ Increasing the concentration of indole-acetic acid in sand-solution tomato cultures decreased ozone injury./ Ozonation of tomato plants caused an alteration in the DNA content of leaves particularly at deficient and superoptimal phosphorus levels./ Analyses indicated higher lignin, cellulose and carbohydrate in needles of pollution resistant Austrian pines than in needles of susceptible strains. ATP content of ozonated tissue increased immediately over untreated tissue, and after 3 days it decreased significantly.

SUPPORTED BY U.S. Dept. of Agriculture

1.0366, FACTORS IN RESPONSE OF AUSTRIAN PINE TO AIR POLLUTION

E.G. BRENNAN, Rutgers the State University, School of Agriculture, *New Brunswick, New Jersey* 08903

We propose to identify the pollutant responsible for observed damage to Austrian pine needles in certain areas of New Jersey and to determine the underlying morphological or physiological factors responsible for observed individual differences in susceptibility. An effort will be made to determine the heritability of these characteristics.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0367, EVALUATION OF POTATO VARIETIES

J.C. CAMPBELL, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00357)

OBJECTIVE: Evaluate new potato seedlings for plant type, tuber type, yields, total solids, market quality, and processing qualities. Evaluate varieties, seedlings, and genetic lines for type and degree of damage from air pollutants. Determine seed-piece spacing, and nutritional needs of new potato varieties.

APPROACH: Seedlings and newly-named varieties will be secured and planted at three locations and data obtained on grades, yields, and specific gravity for market acceptability and samples will be evaluated as baked, boiled, mashed, chipped, and French fried potatoes. Promising new varieties will be planted at various spacings to ascertain the best spacing. Various rates of fertilizer will be applied to determine the most suitable rates and/or methods of application.

PROGRESS: One Canadian and 8 new USDA seedlings produced excellent yields of U.S.01's. Raritan, Lenape, Pennchip, Superior, Kennebec and Norchip yielded from 363 to 327 cwt/A. 29 varieties out-yielded Katahdin. The specific gravity of all varieties was low, but S.G. of Raritan and Lenape was 1.0750 and 1.0742 respectively. Top yields were produced by BR6312-2, Kennebec, Norchip, BR5946-9 and Raritan and 15 varieties out-yielded Katahdin. S.G. of Raritan was 1.0706, but S.G. of all other varieties was low. Yields of over 300 cwt/A were produced by 9 varieties. Yields of Lenape Kennebec, Norchip and Jewel were 388 cwt or more. S.G. of Raritan and lenape were 1.0675 and 1.0672, other were very low. Top yields were produced by Kennebec, Norchip, Raritan, Jewel, Superior, and Chippewa. An air pollution evaluation study was conducted. 10 male and 10 female parents and 4 progeny of each cross were examined for air pollution injury. Injury was very slight to moderate. Seed of Lenape, Superior, Wauseon, and Raritan were spaced 8, 10, and 12 inches apart. Raritan gave highest net yield at 8'. The other varieties gave highest net yields at 10' spacing. Increasing rates of N from 50 to 150 lbs/A and k(2)O from 0.200 lb/A increased yields of Lenape, Raritan and Superior but increasing p(2)05 from 100 to 200 lb/A did not.

1.0368, RELATIONSHIP OF LEAD IN THE AIR, SOIL AND PLANTS TO PROXIMITY TO HIGHWAY TRAFFIC

R.H. DAINES, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00388)

OBJECTIVE: Determine the influence of highways of varying traffic loads on the lead content of soils and vegetation in their vicinity, and determine the area influenced. Determine the effect of lead in the soil coming from various sources on the lead content and distribution within plants.

APPROACH: Grow plants in a greenhouse having lead free air, in soils of varying lead content. Study amounts absorbed and distribution in plants. Grow plants in acid washed sand in greenhouse and at various stations along highways. Pots to be sealed so as to admit only filtered air. Such plants to be studied for lead content and distribution. At each plant growing station air to be sampled and analyzed for lead content. In addition samples of vegetation and soil to be collected at varying distances from highways. These samples to be analyzed for lead content, analyzed for trends that may or may not suggest lead pollution coming from tetra ethyl lead in gasoline.

PROGRESS: A relationship exists between traffic volume, proximity to the highway, engine acceleration vs constant speed, wind direction, and the amount of lead in the air. A marked effect of traffic on the lead content of the air is limited to a zone bordering the lee side of the highways. A decrease of 50% of lead in the air occurred between 10 and 150 ft. from the highway. Beyond

250 feet a decline of lead occurs. Lead values can be expressed as a quadratic function in time and linear to traffic volume. 65% of the lead in the air between 30 and 1750 feet from a highway consists of particles under 2 microns, and 85% under 4 microns in diameter. Soils and plants lead contents tend to increase with traffic volume and decrease with distance from the highway. Much of the lead was present as a removable surface contamination. The major effect of traffic was limited to the surface soil and to a narrow zone within 100 feet of the highway. Plants grown in the field contained the most lead in the aerial portion and those grown in the greenhouse had the most lead in the roots.

1.0369, AIR POLLUTION PROBLEMS IN THE NORTHEAST
R.H. DAINES, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00389)

Objective: Determine the meteorological conditions that permit the accumulation of oxidant air pollutants in excessive concentrations. Determine if pollution episodes result from pollutants generated in a given metropolitan area (local), from pollutants from other areas; or from a combination of pollutant from both sources.

Approach: Air pollution episodes will be determined by Mast ozone recorder (SO_2 removed) and by response of oxidant sensitive plants. When the Mast ozone recorder inicates a pollution of 5 pp.h.m. and above and/or when Bel W. tobacco or White Cascade petunia show visible damage, the results will be reported to predetermined cooperators in the N.E. Region. Plants will be grown in charcoal filtered greenhouses. Our reports and those from others cooperating in the Northeast will be studies to determine meteorological parameters that characterize air pollution episodes. Efforts will be made to differentiate between parameters that result in pollution from local sources and those that favor the transportation of pollutants from other areas.

Progress: Plant response was significantly influenced by the relative humidity of the atmospheres. At high humidity (95%) wet or dry Bel W3 tobacco plants exhibited similar and pronounced injury at a 90 minute exposure at 0.15 ppm ozone. At 51% relative humidity 0.30 ppm O_3 was required to produce injury of similar intesnity. At 26% relative humidity 0.35 and 0.4 ppm O_3 was required to produce equivalent plant response. Pinto beans exhibited similar response. Porometer readings demonstrated that humidity affected the leaf permeability or stomatal openings with the stomata on leaves exposed to the lowest humidity exhibiting the least permeability and the highest humidity showing the greatest permeability or stomata showing the largest openings. This provides one reason why plants in the Northeast are more readily injured by air pollutants than are similar plants in the Southwest. Since all pollutants enter the leaf through open stomata, the relative humidity should influence susceptibility. Fewer plant damaging episodes were observed in the field last year.

1.0370, STUDY OF IRRADIATED AIR POLLUTANTS ON SPREAD FILMS
A. FELMEISTER, Rutgers the State University, School of Pharmacy, *New Brunswick, New Jersey* 08903

It is the purpose of this project to: (a) continue the study of the adsorption of non-irradiated and irradiated air pollutants on various spread films in order to gain additional insight into both the site and mechanisms of action of gaseous air pollutants on biomembranes; (b) investigate the influence of air pollutants on active enzymes and enzyme -lipid complexes spread as monomolecular films. It is anticipated that this will lead to a better understanding of the mechanism of enzyme inhibition by pollutants; (c) study the properties of various monolayers, after interaction with pollutants; (d) investigate the effect of certain additives, such as antioxidants and materials known to influence cell membrane stability and permeability, on the adsorption of air pollutants on spread films; and (e) develop further the relationships between the pollutant-film interactions and the biological response observed with simple organisms.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0371, RELATIONSHIPS BETWEEN CERTAIN AIR POLLUTANTS AND VARIOUS METEOROLOGICAL FACTORS
A.V. HAVENS, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00279)

OBJECTIVE: Determine the relative importance of various climatic parameters in relation to the occurrence of pollution conditions over New Jersey. Develop a mathematical relationship between levels of pollution concentration and the diffusive power of the atmosphere. This study will utilize data on $S(2)$ concentration, suspended particulate matter and related meteorological observations which have been collected over a 6-year period and made available through the cooperation of a local industry and the U. S. Weather Bureau.

APPROACH: Evaluation of a statistical model and preparation of additional publications is planned. Improvement in the prediction capability could be achieved by further model evaluations on the basis of standard forecasts by U. S. Weather Bureau. This would indicate the utility of the model as a practical forecasting tool.

PROGRESS: The concentrations of air pollutants are often highest in the early morning hours when winds are light and the atmosphere near the ground is thermally stable due to the presence of a temperature inversion. Under such stagnant conditions atmospheric dilution is at a minimum. By early afternoon, however, pollutant concentrations are usually at a minimum because of turbulent mixing of the lower atmosphere by thermal convection when the ground is warmed by bright sunshine. The effectiveness of this daytime dilution is largely dependent upon the depth to which the atmosphere is mixed by thermal convection and wind since this mixing depth determines the volume of air into which pollutants are dispersed. In this study, daily temperature and wind profiles over the New York City and Philadelphia are being correlated with hourly observations at New Brunswick and 24 other locations in and around New Jersey in an effort to develop a method for predicting the mixing depth and ultimately atmospheric dilution from readily available and inexpensive ground-level observations rather than expensive radiosonde soundings. This will be especially useful in areas located a considerable distance away from the nearest radiosonde station.

SUPPORTED BY U.S. Dept. of Agriculture

1.0372, AIR POLLUTION
A.J. KAPLOVSKY, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00526)

OBJECTIVE: Determine the rate, extent, and mechanism of absorption of low concentrations of sulfur dioxide by various textile materials.

APPROACH: Study of sulfur dioxide absorption by textile materials. The work will be continued with the procedures developed up to the present; namely, exposing the textile materials to controlled and confined dynamic atmospheres containing known amounts of $SO(2)$ moisture and to determine the removal of this gas and the effect of the environmental factors, the reactions involved, and the effects produced on the textile materials.

PROGRESS: A study of behavior of solid submicron aerosol particles in helium and argon gases as influenced by particle charge and presence of water vapor. Specific experimental system designed for diffusion measurements of poly-dispersed aerosols. Knowledge of physical forces (charge, particle size) in formation of fog and dissipation needed to study relationship to pollution and control. Liquid aerosol formed by attachment of water vapor to tungsten particles and observed change in measured particle size diameter. Scattered light measurement indicated liquid aerosol formed when either of the zero time tungsten aerosols were used as condensation nuclei. No size change detected. Results confirmed by Goetz Aerosol Spectrometer measurements. Generation of E. coli by evaporation from distilled water and collection with particle sizing prior to aerosolization and after collection showed noted difference in cell size. Analysis of particle size distribution by mathematical frequency functions completed.

SUPPORTED BY New Jersey State Government - Trenton

1.0373, EFFECTS OF AIR POLLUTION ON A FOREST ECOSYSTEM
T.H. NASH, Rutgers the State University, School of Arts, *New Brunswick, New Jersey* 08903

Pollution of air, soil and water is an environmental problem of widespread and critical importance to the health of man and the quality of his environment. Uncontrolled pollution may well exact its heaviest tool through the poisoning and disruption of delicately balanced local and global ecosystems. It is the broad objective of this research to investigate the role of air pollution as a biological stress on a natural forest ecosystem, and to study the effects of this pollution on the species composition, succession, productivity and diversity of the forest. The physiological responses of the cryptogams will also be considered. Results from the study will have importance in assessing the economic and aesthetic value of the area.

The study site is the Lehigh Water Gap area of Blue Mountain, near Palmerton, Carbon County, Pennsylvania. The situation is ideal for studying the long-term effects of pollution. A zinc smelter, located in Palmerton since 1898, is the only main source of pollution (sulfur dioxide and heavy metals) for many miles, thus creating a built-in experimental and control area. The past history of the land, the smelter and the forests is reasonably well known, and meteorological data are available since 1918.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0374, ENVIRONMENTAL REQUIREMENTS OF POULTRY
C.H. REED, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00567)

OBJECTIVE: Determine the effect of environmental components on the productive performance and various physiological measurements of poultry. Factors of environment that may be studied include: Heat level. Moisture level. Air movement.

APPROACH: Parameters for measuring these effects will be feed consumption, body-weight grains, mortality, blood volume and composition, and biochemical changes in body composition that are representative of protein metabolism within the cells of several tissues, such as serum, intestine, liver and muscle. These tissues represent 95% of protein metabolism within the animal body.

PROGRESS: Studies on the effect of air pollution (dust) and 4 light regimens (black, natural, 454 and 653 mu) on protein metabolism in immature fowl are part of a series in cooperation with the Universities of Maine and Vermont. Tissues of rapidly growing chicks reared under these experimental treatments were analyzed for protein, nucleic and free amino acids - parameters considered reflective of protein metabolism in this 'anabolic' model. Within the experimental period, liver DNA and RNA concentrations were significantly increased by moderate dust treatment; protein and free amino acids were not affected. Compared to controls, liver weight was less under black light and 454 mu. Light regimen did not affect concentrations of liver protein, DNA, RNA and free amino acids. Heart weight was significantly less under black light and greater under 653 mu. DNA concentrations were higher under 454 mu; protein, RNA and free amino acids were not affected. Total quantities of heart DNA were depressed under black light and increased under 454 and 653 mu. Black light lowered total protein and free amino acids.

1.0375, OZONE AND VASCULAR TISSUE DIFFERENTIATION IN PLANTS
J.P. RIER, Rutgers the State University, School of Arts, *New Brunswick, New Jersey* 08903

This is an investigation of the possible effects of sublethal dosages of ozone on differentiation of xylem and phloem in callus tissue and whole plants. Plant tissues grown in vitro and whole plants in vivo treated for vascular tissue induction will be exposed to ozone at a variety of concentrations and durations. Following these treatments, tissues will be examined histologically for anatomical changes and electrophoretically for possible associated changes in the quality of proteins.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0376, THE CHIRONOMIDAE OF CALIFORNIA
L.E. SUBLETTE, Eastern New Mexico University, Graduate School, *Portales, New Mexico* 88130

The family Chironomidae has an unusual ecological valence which ranges from low to high pollutional tolerance. For more precise ecological management of freshwater, we must accumulate a considerable body of knowledge of the group. The following subprojects will identify the major points of study: (1) Life history studies through rearing of immature stage; (2) Cytotaxonomy of the genus 'Chironomus' with particular reference to the 'attenuatus' and 'riparius' (equals thummi) groups; (3) Completion of a review of the Orthocladiinae of California; (4) Preparation of a handbook of the family for the California Insect Survey.

A bulk of the field work will be performed in California by Mr. Frommer.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

1.0377, INTERACTIONS BETWEEN THE GREAT LAKES AND THE ATMOSPHERE
R.J. PILIE, Cornell Aeronautical Lab. Inc., *Buffalo, New York* 14221 (001129)

Approach: Present results indicate that the scope of the Great Lakes Snow Storm Experiment must be conducted on a larger scale so as to encompass the fundamental problems of mesoscale modification, seeding agent diffusion, city influence on weather and the increase, decrease, and/or redistribution of snowfall due to seeding. The FY-71 program will be transitional, with major emphasis directed toward expanding the overall scope of the experiment, preparatory to an expanded fild effort in FY-72.

Progress: The results of this year's experiment were: a. The previously developed mesoscale numerical model has been found to agree markedly well with the natural cloud systems, b. The basic seeding hypothesis, namely redistribution of snowfall, and overseeding, appears confirmed by surface observations of the snowfall; and c. Conditions have been demonstrated where heavy snow showers can be released artificially be airborne or ground seeding or by 'city plume'.

1.0378, AIR POLLUTION PROBLEMS IN NORTHEAST
B.E. DETHIER, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00080)

OBJECTIVE: Determine the impact of present air contaminants on the agriculture of the Northeast and to obtain information prerequisite for the development of air quality criteria as they relate to agriculture in the Northeast.

APPROACH: Collect data on air quality and air quality effects for compilation in the regional survey of the degree and economic importance of air pollution damage to agriculture and apply statistical weather records to estimation of frequency and duration of pollution episodes and investigate factors underlying changing pollution concentrations in the air mass.

PROGRESS: Lack of electrical power due to the relocation of the weather station prevented the monitoring of oxidant levels during the mid summer. Bel W-3 tobacco plants grown in filtered air were used as indicators during the entire summer. Some non-typical damage was observed for a short period on some plants located within 50 ft. of a construction site. Other plants a few miles away were uneffected. Oxidant levels, during all monitored periods remained below 2 pphm. Temperature differentials between two levels and wind speed and direction were recorded continuously on the 250 ft. meteorological tower. Since no pollution episodes were observed during the summer, the weather data is being used to continue the investigation of the formation and breakup of inversions.

SUPPORTED BY U.S. Dept. of Agriculture

1.0379, EFFECT OF AIR POLLUTION - MICROBES IN VIVO AND IN VITRO
G. STOTZKY, New York University, Graduate School, *New York, New York* 10003

1. AIR QUALITY

The effects of various air pollutants on growth, survival, spore germin-ation, adaptation, etc. of microorganisms in pure culture, in soils, and on plants have been studied. Differences in sensitivities between groups and species of microorganisms were observed, but sensitivity of all microbes to O sub 3 was several magnitudes greater than to SO sub 2 and H sub 2 S.

The objecties of the proposed research are: (1) to determine further the effects of air pollution on microbes in pure culture and in natural habitats, such as in soil and on plants; (2) to determine the mechanisms whereby air pollutants affect microorganisms; (3) to determine whether microbes can be used as a bioassay of air pollution; (4) to develop better methods for evaluating the effects of air pollutants on microorganisms; (5) to determine whether and how natural habitats offer protection to microbes against the detrimental effects of air pollution; (6) to determine further whether and how microbes metabolize some air pollutants.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0380, AIR POLLUTION EFFECTS ON POWDERY MILDEW FUNGI

C.R. HIBBEN, Brooklyn Botanic Garden, *Ossining, New York* 10562

The effects of ozone and sulfur dioxide on powdery mildew fungi will be investigated by exposing conidia on artificial and natural substrates to acute and chronic gas doses under controlled environmental conditions. The reaction to the gas treatments will be assessed by determining spore germination, morphological characteristics of the germ tubes, substrate colonization, and sporulation. The influences of temperature, relative humidity, light, and nutrients on the reaction of the fungi to the gas treatments will be determined. In addition, the protective effect against the gases by leaf tissue infected by powdery mildew fungi will be elucidated.

1.0381, MULTIPLE LIGHT SCATTERING OF POLLUTED ATMOSPHERES

M. KERKER, Clarkson College of Technology, School of Arts, *Potsdam, New York* 13676

The reduced visibility in a polluted atmosphere is due to the muliple scattering of light by aerosol, in addition to the molecular scattering. For a real atmosphere containing both aerosol and molecular scatterers, the calculation is prohibitively long. This study comprises a systematic laboratory investigation of multiple scattering together with a massive computational program.

The first phase of this project, which is now just about completed, has involved (1) the construction of a multiple scattering photometer, (2) an experimental study of polystyrene latex which simulates the aerosol component of the atmosphere, and (3) comparison of the experiments with computations. This has established that our experiment can serve as an 'analog computer' for atmospheric scattering.

The proposed work will comprise three phases consisting of (1) a similar study with colloidal silica to simulate the molecular component of the atmosphere, (2) a study of synthetic mixtures of polystyrene latex and colloidal silica which will simulate real atmospheres, and (3) an attempt to solve the inverse problem of deducing the aerosol content from scattering data.

Thus, not only will the optical effects of loading the atmosphere with aerosol be amenable to accurate and rapid study, but the optical measurements can lead to information about the aerosol content.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0382, BEHAVIORAL PHARMACOLOGY AND TOXICOLOGY

B. WEISS, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

Behavioral techniques are being employed to study the effects of toxic agents which act primarily on the central nervous system. One reason is that in many instances the primary impairment is behavioral; the second reason is that disturbances in central nervous system function are often best reflected in behavioral situations. The basic method is to train animals to perform in behavioral situations which permit a specific function to be studied, for example, the capacity to alter behavior as a function of specific stimuli; the ability to perform motor tasks requiring fine motor control. Digital computers are used both to control the experiments and to analyze the results. A wide range of species are studied, including man. Agents currently being assessed include mercury, carbon monoxide and chemicals affecting brain amines.

Results: In rats, 400 ppm CO produced changes in the ability to respond to stimuli associated with the passage of time. Experiments with monkeys suggest that discriminative motor control is impaired by exposure to 1 mg/per cubic m of mercury six hours per day for six months. A similar task with humans exposed to mercury vapor in industry shows the method to be applicable here, too. In studies involving dogs, squirrel monkeys, and pigeons, changes in performance have been observed at dose levels of drugs such as amphetamine and alpha-methyltyrosine which probably have little effect on catecholamine levels in brain.

SUPPORTED BY U.S. Atomic Energy Commission

1.0383, EFFECTS OF AIR POLLUTANTS ON PLANT SYSTEMS

L.H. WEINSTEIN, B. Thompson Inst. Plant Res., *Yonkers, New York* 10701

The following studies are proposed for the 1971-72 fiscal year: 1. A second interlaboratory study of fluoride in vegetation will be completed and results will be published. 2. A new method of direct analysis of fluoride in vegetation using the fluoride ion specific electrode will be subjected to an interlaboratory study. 3. Tests will continue to develop a continuous fluoride air monitor. 4. The effects of environmental factors such as humidity, light intensity, and length of photoperiod on the response of plants to fluoride will be studied. 5. Apparent photosynthesis and transpiration of intact plants exposed to air pollutants will be studied. 6. Experiments will be carried out to establish the mechanism of synthesis of fluoroacetic acid in 'Acacia georginae.' 7. The metabolism of sulfur dioxide in plants in relation to the activity of sulfite oxidase will be studied. 8. Studies will continue on senescence in plants as related to exposure to air pollutants. 9. The rate of absorption of SO2 by foliage of urban trees will be continued.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0384, EFFECTS ON FOREST TREES OF LONG-TERM EXPOSURE TO LOW CONCENTRATIONS OF AIR POLLUTANTS

C.R. BERRY, U.S. Dept. of Agriculture, S.E. Forest Experiment Station, *Asheville, North Carolina* 28802 (SE2305)

OBJECTIVE: Determine symptoms and susceptibility of forest tree species to injury by air pollution; extent to which clones can be used as indicators of air pollution; select and breed trees resistant to specific pollutants.

APPROACH: Surveys of air pollution damage to eastern white pine in the Asheville, N.C. area and study of resistance to coal smoke injury of progeny from resistant parental trees. Develop biological air pollution indicator clones; determine agent causing emergence tipburn of eastern white pine, and whether other species can be affected, and relative susceptibility of various forest tree species to different types of air pollution.

PROGRESS: In the first phase of bioindicator work, 1,439 white pine seedlings were screened in the field and 435 exhibited specific sensitivities to 3 different air pollution regimes predominantly SO(2), fluorides, or oxidants. Sixty-four seedlings were resistant to all air pollution regimes. Acute injury was induced on field-grown white pines by exposures to ambient SO(2) at concentrations of 5 p.p.h.m., or higher, lasting 4 hours. No field injury could be associated with fluctuations in O(3) although concentrations never exceeded 4 p.p.h.m. Average daily ambient SO(2) concentrations increased from summer to winter while O(3) concentrations decreased. White pines were injured less with an O(3)-SO(2) mixture in 2-hour artificial exposures of 5 p.p.h.m. of each gas than with 5 p.p.h.m. of SO(2) alone. Effects on growth have been studied by comparing trees or branches grown in fil-

tered and unfiltered air. Needle growth of sensitive white pines exceeded needle growth of resistant white pines when grown in filtered air indicating that the fastest growing trees in clean air may be those injured most by polluted air.

SUPPORTED BY U.S. Dept. of Agriculture

1.0385, BIOCHEMISTRY OF OZONE INJURY TO PINES
R.L. BARNES, Duke University, School of Forestry, *Durham, North Carolina* 27706

The broad objective of my research project is to study the effects of ozone on the metabolism of two important pine species--white pine (Pinus strobus L.) and loblolly pine (P. taeda L.). Emphasis will be on (1) basic physiological and biochemical responses to ozone exposures under controlled environmental conditions, and correlations of these responses with visible injury symptoms; and (2) the effects of controlled environmental preconditioning on sensitivity to ozone.

Two possible applications of such fundamental information will also be explored: (1) The use of biochemical and physiological knowledge to improve the usefulness of pines as bio-indicators of ozone as an air pollutant in the field. (2) The improvement of methods of handling and testing tree materials in controlled-exposure investigations.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0386, EFFECTS OF OZONE ON SELECTED MATERIALS
N. BELOIN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To establish damage functions for the effects of ozone on selected materials under field conditions.

Approach: Strained white sidewalls, paint, and plastic samples will be exposed in semi-open field chambers into which controlled levels of ozone are introduced. Damage will be assessed and correlated with ozone levels.

Goals: Expose materials and assess short term damage.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0387, EFFECTS OF PARTICULATES ON SOILING OF BUILDING MATERIALS
N. BELOIN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To correlate soiling of building materials with measured levels of suspended particulates.

Approach: Three sites each in Birmingham, Alabama, and Buffalo, New York will be used to expose prefinished siding materials. Particulate levels will be monitored and reflectance measurements will be made at intervals.

Goal: Continue to expose materials and take measurements.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0388, DESIGN OF GROWTH AND EXPOSURE CHAMBERS
D. BODY, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Design, build, and test field exposure chambers, growth chambers, and exposure chamber inserts for greenhouse and growth chambers.

Approach: Presently acceptable closed top field chambers are in operation based on past design and field tests. Continued design and testing is planned to determine the feasibility of constructing and using open top chambers for field exposures designed to test the impact of ambient pollution on plants, or to use for pollutant additions both singly and in combination under field conditions. Additional testing of several closed top designs will be accomplished for the same purposes. Design of acceptable growth chambers is completed and component parts have been purchased. A prototype chamber will be built and tested. Special inserts for these chambers and for greenhouses have been designed and built, they will undergo additional testing.

Goals: Design, build, and field test open top field exposure chambers; build and test growth chambers for controlled experimental work.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0389, GLACIER NATIONAL PARK ABATEMENT STUDY - ASSESSMENT OF VEGETATION EFFECTS
K.E. FOSTER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Conduct a survey of damage to vegetation in Glacier National Park and vicinity. Confirm cause of damage by chemical analysis of fluorides in vegetation and by morphological examination. Determine atmospheric fluoride concentration at four sampling sites. Expose selected vegetation specimens in environmentally controlled chambers at four locations. Establish a limited network of static fluoride sampling devices. Prepare a report of findings for use by the Dept. of Interior.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0390, SURVEY OF PLANT RESPONSES TO AMBIENT POLLUTANTS
A.S. HEAGLE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Determine visible injury symptoms from ambient pollution on plants grown in the field.

Approach: Plant species and/or varieties will be planted out to determine their response to ambient pollution levels in the Raleigh area. Detailed notes will be taken to varied time periods and results compared with those found in Cincinnati. Injury will be correlated with monitored environmental parameters. Varietal studies on University farms will be periodically surveyed for injury.

Goals: Determine visible injury symptoms from ambient pollution on 10-15 species and/or varieties of plants planted under field conditions.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0391, RESPONSE OF PLANTS TO ACUTE DOSES OF POLLUTANT MIXTURES AT SPECIFIC GROWTH STAGES
A.S. HEAGLE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Determine the effect of acute exposures to pollutant mixtures of plants grown under field or greenhouse conditions, when exposed at given times during the growth cycle.

Approach: A replicated field design will be established for exposing plants at 2 week intervals throughout the growing season. Plants will receive from 1 to 6 acute exposures to mixtures of the 2 gases at the different time intervals to determine the impact of time of acute exposure and number of exposures on total growth, reproductive capabilities and yield. Time-concentration-injury equations will be developed under greenhouse conditions for a selected group of plants exposed for 5 time periods at 2 concentration mixtures of ozones and sulfur dioxide.

Goals: Determine response of 10 plant species and/or varieties grown under field and/or greenhouse conditions to mixtures of ozone and sulfur dioxide.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0392, RESPONSE OF PLANTS TO INTERACTIONS BETWEEN PATHOGENS AND OZONE
A.S. HEAGLE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objectives: Determine the effect of interactions between pathogens and ozone on the host species, when the host is grown under greenhouse or field conditions.

Approach: Selected species of crop plants will be grown in field plot designs or under controlled conditions. At varied times the plants will be inoculated with a given pathogen or exposed to ozone and the reverse procedure run on either the inoculated or the exposed plants. Some of the designs will include the inoculation before and after fumigations. Some will include an ozone fu-

migation before and after inoculation. Each study will be replicated for statistical analysis. The effects of the interaction of the pathogen with ozone on the host plants will be documented. The field studies will be used to determine the effects off ozone on disease severity, prevalence, growth and yield of the host. Both facultative and obligate pathogens will be used. As a spin-off from this project, we will determine the direct effects of ozone on host-parasite interactions.

Goals: Determine the effect of 3 host species (oat, barley, tobacco) of interactions between pathogens and ozone using several exposure times and ozone concentrations when experiments are carried out under both field and greenhouse conditions.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0393, EFFECT OF NATURAL GAS ON SOIL ECO-SYSTEMS IN AN URBAN ENVIRONMENT
A.S. HEAGLE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Determine effect of natural gas leakage from gas mains on soil eco-systems including ornamental plantings.

Approach: Preliminary surveys have shown a severe natural gas leakage from gas lines along several boulevards in downtown Wilmington, N.C. Gas releases have been reported from time to time in other older large cities. In Wilmington, continuous loss of tree plantings along these boulevard has resulted. Preliminary studies have shown poor soil acration and low nematode counts. It was deemed advisable to determine whether natural gas acts directly or indirectly on the soil atmosphere to cause death of these ornamental city trees. Experimental field plots have been set up Wilmington. Soil samples have been set in Wilmington. Soil samples have been obtained for greenhouse studie and selected plants grown in these soils. Greenhouse experimental designs have been set up to determine the effect of natural gas on root systems of selected species. If natural gas is the cause, such a problem might develop in many eastern cities where natural gas lines are 50 to 100 years old. These studies will be combined with preliminary studies on levels of certain gasoline additives in plant species along heavily traveled and lightly traveled throughfares within Wilmington.

Goal: The results of the first year's study on effect of natural gas on soil eco-systems of urban area will be completed. The second year's study will be planned and initiated.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0394, TECHNICAL ASSISTANCE IN AIR POLLUTION PROBLEMS RELATED TO AGRICULTURE
W.W. HECK, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Give technical a sistance to requesting agencies and individuals in air pollution problems related to agriculture.

Approach: Technical assistance will be given to other Federal, State, and Local agencies and to individuals who have problems relating to the effects of air pollution on agricultural crops and other commodities. This is an on-going responsibility of the Agriculture Branch and includes responses to inquiries on injury, contact with county agents to ascertain the nature and extent of injury, and site visits to determine the cause of injury and discuss the methods of correcting the problem.

Goals: Continue to give requested technical assistance in air pollution problems related to Agriculture as time permits.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0395, AGRICULTURAL-POLLUTANT REPRINT LIBRARY
W.W. HECK, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Develop a complete reprint library on articles covering the effects of air pollutants on native and domestic receptors.

Approach: The development of an adequate reprint library to cover air pollution aspects of injury to vegetation was initiated sometime ago and its nature and function discussed with APTIC. Addition to the file is through a numbered system related to the alphabetical author index. Cross-referencing by subject has been extensively done using key-words. The file is currently being updated and contains over 2500 reprints at this time. At the present rate of effort, we should complete our search for this type of article sometime late in FY 71 and should initiate a search and development for articles relating to domestic animals. APTIC will have access to our file for their use and we would expect them to furnish reprints to other investigators.

Goals: The reprint library will be up-to-date in relation to articles on effects of air pollutants on vegetation.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0396, THE RELATIVE SUSCEPTIBILITY OF WESTERN CONIFERS TO OZONE AND AMBIENT OXIDANTS
W.W. HECK, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objectives: Determine the sensitivity of western conifers to the photochemical complex.

Approach: Several species including fir, spruce and pines, at several different growth stages, will be exposed to different levels and times of components of the photochemical complex and to the ambient pollution of the Los Angeles basin. The degree of injury, the reduction in yield, reduction in growth, and projected reduction in timber yields will be determined from this study.

Goals: Determine the relative susceptibility of 10 selected western conifers to the photochemical process.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0397, RESPONSE OF SELECTED FIELD PLANTS TO AMBIENT POLLUTANTS IN WASHINGTON, D.C.
W.W. HECK, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Determine the effects of ambient Washington, D.C. air on ornamental crop species.

Approach: Large greenhouses equipped to remove pollutants from ambient air or to admit unfiltered air are being used in the Washington, D.C. area. Four small houses are being built for replicated studies using filtered and non-filtered ambient air in this area to determine the effects of ambient pollution mixtures on selected groups of crop and ornamental species. The research here will be aimed at determining the effects of pollutants on visible injury, growth, yield, reproductive capabilities, and quality of crop produced. Work with field grown crops will be stressed.

Goals: Determine the effects of ambient Washington, D.C. air on 15 ornamental and field crops.

SUPPORTED BY U.S. Environ. Protect Agency - N.A.P.C.A.

1.0398, RESPONSE OF EASTERN CONIFERS TO POLLUTANT MIXTURES AT SPECIFIED TIMES DURING NEEDLE DEVELOPMENT
W.W. HECK, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Determine the effect of pollutant mixtures on Eastern conifers when exposed to various times and concentrations of pollutants under varied nutritional conditions.

Approach: A selected group of Eastern conifer species will be screened for their susceptibility to acute and long term effects of three combinations of ozone and sulfur dioxide. Survival, reproductive capabilities, injury, and growth effects will be determined.

Goals: Determine the effect of ozone and sulfur dioxide mixtures on 10 Eastern conifers exposed to various concentrations and times of pollutants under several nutrient regimes.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0399, MT STORM - W VIRGINIA - GARRETT COUNTY - MARYLAND ABATEMENT ACTION - FIELD INVESTIGATION
T. HELMS, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Conduct a field investigation designed to define the extent and cause of damage to Christmas tree plantations in the interstate area. Transplant trees to and from plantations remote and close to the suspected principal source of pollution. Deploy selected vegetation in environmentally controlled chambers. Monitor ambient air for content of SO2, NOx, O3, and F at three locations. Deploy a network of static sampling devices to determine relative geographic distribution of SO2, F, and dust-fall. Analyze vegetation samples for content of F and S. Prepare a preconference report and participate in abatement conference.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0400, DETERMINING CAUSE OF DAMAGE TO COTTON PLANTS IN BIRMINGHAM, ALABAMA
HINDAWI, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Make visual inspection of damage to cotton plantations in Birmingham area. Analyze damaged vegetation chemically, morphologically, and microscopically to determine nature of the pollutant causing the damage.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0401, STUDIES TO DEVELOP DIAGNOSTIC TECHNIQUES FOR EVALUATING INJURY TO VEGETATION
R. REINERT, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Determine the chemical and morphological response of plants to pollutants to help in the development of diagnostic tools for evaluating the injury to plants.

Approach: Tissues from plant species will be grown and exposed under a variety of conditions to determine the effects of pollutants and pollutant mixtures on various systems of the plant tissues. Selected whole plants (soybean and tobacco varieties) will be grown to specific growth stages and exposed under greenhouse or controlled exposure conditions to pollutant mixtures. Changes in morphology, histochemistry, respiration and gross quality will be determined and related to exposure concentrations and times.

Goals: From greenhouse and controlled exposures of mixtures of pollutants, determine effects on tissue growth and development, on morphology, histochemistry respiration and certain chemical constituents of selected plant species.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0402, LOW CONCENTRATION-LONG TERM RESPONSES OF PLANTS TO POLLUTANT MIXTURES
R. REINERT, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Determine the response of plants to pollutant mixtures when exposed under field or greenhouse conditions throughout the growth cycle.

Approach: Following established experimental design the selected group of crop and ornamental species will be exposed to 2-3 mixtures of sulfur dioxide and ozone for 6 hours per day over the entire developmental cycle of the plants. Growth and injury will be recorded on a weekly basis through this growth cycle and effects of pollutant combinations on reproductive capacity and reproductive structures will be determined as well as the effect on yield and quality of final product. Field exposures will be made in special chambers using 2-4 species or varieties per chamber. Each treatment will be replicated 4 times. A field plot having no chamber will be used to determine chamber effects. Greenhouse exposures will be made in standard greenhouse exposure chambers following accepted protocol.

Goals: Determine the effects of low level mixtures of sulfur dioxide and ozone on symptom development, growth, reproductive capacity, and yield from 10 selected field and vegetable crops under field and/or greenhouse conditions.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0403, ACCUMULATION OF HEAVY METALS IN PLANTS NEAR LOW AND HIGH TRAFFIC DENSITIES
R. REINERT, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Determine the effect of traffic densities on the accumulation of heavy metals in plants.

Approach: A detailed research design will be developed to determine the concentration of heavy metals which might accumulate in ornamental and tree species in the vicinity of highly traveled roadways as a result of automobile release. The possible effect of heavy metal accumulation will be correlated with leaf injury and early senescence of urban ornamental vegetation.

Goals: A systematic collection of plant tissues in high and low traffic density areas will be made in several major urban areas and analyzed for heavy metal accumulation during the 1971 growing season.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0404, EFFECTS OF SELECTED PESTICIDES SINGLY AND IN COMBINATION WITH OZONE ON SELECTED PLANT SPECIES
D. TINGEY, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Determine the effects of pesticides on selected plants as these effects are modified by other pollutants.

Approach: This project will be initiated as a literature review, report preparation, and state of the arts type of effort, to determine what we know and what research needs to be planned in the area of pesticide-pollutant interaction. Initial research will utilize two selected plants, which are sensitive to a specific herbicide. These plants will be grown and exposed to both the herbicide and to ozone, as an air pollutant, at a given stage of growth and at 2 ozone concentrations. Plants will be exposed to ozone prior to, at the same time as, and after exposure of the plant to the selected herbicide. This project will allow some input into the area of pesticide-pollutant interactions, as they affect plant response.

Goals: A detailed literature survey will be completed and research designed for preliminary studies on herbicide-ozone interactions during the 1971 growing season.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0405, CONTROLLED ENVIRONMENT STUDIES ON METAL CORROSION CAUSED BY AIR POLLUTION
J. UPHAM, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Object: To substantiate field observations, which relate corrosion rates to pollutant levels, with controlled environment experiments.

Approach: Galvanized steel will be exposed to controlled environments containing either singly or in combination SO2, O3, and NO2 at various levels in combination with various temperatures and relative humidities. The damage will be evaluated by conventional methods such as weight loss and less conventional methods such as microprobe analyses.

Goal: Design and initiate laboratory experiments.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0406, ECONOMIC IMPACT OF REDUCED VISIBILITY AT AIRPORTS FROM AIR POLLUTION
T. WADDELL, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To analyze the relationship between visibility reduction at selected airports and accident rates, flight interruptions, and delays in scheduled flights.

Approach: Comparisons will be made between several airports with different levels of visibility problems attributable to air pollution. Data on weather conditions, pollution levels, and visibility reduction will be obtained from local weather stations.

Goal: Document on visibility problems encountered at airports and the associated costs.

1. AIR QUALITY

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0407, PENNSYLVANIA POWER PLANT STUDY
D.E. WEBER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Determine the effectiveness of high stacks in preventing injurious ground level fumigations and evaluate the air pollution problems to agriculture in a rural pollution situation.

Approach: Eight major study sites have been leased in the area of Indiana, Pa., to study the effects of emissions from 3 large power plants on vegetation. Each site has a farm pond, terracing, fencing, and will be equipped for monitoring 4 pollutants, air temperature, wind speed and direction, humidity, soil temperature and soil moisture. Data will be fed into a data acquisition system for computer analysis. Each study plot will contain 5 or 6 tree species and 6-12 species of crop and ornamental plants. Growth, production, and lead sulfates will be determined at the 8 sites. Field chambers will be installed to study the effects of filtered and non-filtered environments. Minor study sites (22) have been established within a 25x50 mile area extending NE from 3 power plants. There are 15 scotch and 7 white pine plantations. Growth changes will be measured on the pine. Sulfur plates and lime paper with measured background levels of SO2 and HF. Detailed observations of native vegetation will be made.

Goals: Complete establishment of 8 permanent study plots for LaPPES and statistical study of 10 environmental parameters monitored for 3 months at each of the 8 sites.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0408, PLANT AIR POLLUTION STUDIES ON LOSSES, EFFECTS, AND CONTROL AND TECHNICAL ASSISTANCE ON PROBLEMS
W.W. HECK, U.S. Dept. of Agriculture, Crops Research Division, *Cincinnati, Ohio* 45226 (0000-06-01)

OBJECTIVE: Determine the economic impact of air pollution on plants; determine the physiological, morphological and biochemical basis of the effects of various air pollutants on plants, study means of protecting plants against air pollutants, provide technical assistance to public and private agencies on plant air pollutant problems.

APPROACH: Study morphological, physiological and biochemical changes in plants exposed to toxic atmospheres, interaction of those with environmental factors, and use of specific symptoms for identification and extent of damage.

PROGRESS: Investigations with gas mixtures have shown synergistic responses between NO(2) and SO(2) on tobacco and between SO(2) and O(3) on five species. A sixth species showed no synergistic effect from SO(2) O(3). These results at low levels of pollutants emphasize the importance of monitoring for several pollutants when studying pollution effects under ambient conditions. Single gas studies must be undertaken with an understanding of possible pollutant interactions. A chlorotic dwarf condition of white pine has been related to known ambient levels of SO(2) O(3) by using laboratory exposure facilities. This work was done in a study with the Forest Service. This interaction suggests that many unexplained needle blights of eastern white pine may be caused by pollutant interactions. Injury - dose curves have been developed for 50 species and varieties to O(3), SO(2) and NO(2). These were developed in exposure chambers under greenhouse conditions using nine concentrations at five time periods. These results will be useful for development of Criteria Documents which will be used to set air quality standards. Research using well controlled growth and exposure conditions have shown an interaction between growth light and humidity on the sensitivity of pinto bean to ozone. Plants are more sensitive to ozone when grown under low light intensities but more sensitive when exposed under high light intensities. Light is more important than humidity in conditioning plants to an ozone response.

SUPPORTED BY U.S. Dept. of Agriculture

1.0409, SOLAR RADIATION AND AIR POLLUTION CLIMATOLOGY
W. BACH, Univ. of Cincinnati, Graduate School, *Cincinnati, Ohio* 45221

The objective of this research is to continue a study of the effects of air pollution on solar radiation. The work began in Cincinnati, supported by NSF grant GA-13683; and, with the move of the principal investigator to Hawaii, will continue in that environment with emphasis on the Honolulu area, the effects of natural pollutants from volcanoes and the effects above clean islands. Comparative studies will be made of these effects with airborne photometers and nephelometers as in the case of Cincinnati.

SUPPORTED BY U.S. National Science Foundation

1.0410, EFFECTS OF ENVIRONMENTAL POLLUTION FROM AIR FORCE MISSILE PROPELLANTS ON PLANTS
C.T. LIND, U.S. Air Force, Aerospace Med. Res. Lab. 6570, *Dayton, Ohio* 45433

Technical Objective: Missile propellants currently in use and those being considered for future application to advanced systems are reactive materials and are toxic to man, animals and plants. Their use in large quantities could result in significant effects on the environment due to spills and contamination by exhaust products. To insure that Air Force missile operations are not disruptive to the ecology of the environment, this effort will determine the effects of selected missile propellants on a wide variety of plant species and develop environmental pollution toxicology criteria for Air Force Compliance with all federal pollution regulations, Executive Orders, and AFR 161-22.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0411, ENVIRONMENTAL POLLUTION TOXICOLOGY OF AIR FORCE MATERIALS
A.R. SLONIM, U.S. Air Force, Aerospace Med. Res. Lab. 6570, *Dayton, Ohio* 45433

Technical Objective: Various Air Force missile propellants and other chemicals are potentially serious environmental pollutants. The objective of this work unit is to provide information on the effect of these chemicals and their degradation products on the environment. This information is basic to provide environmental pollution toxicology criteria for Air Force directives on the handling, use, disposal, and decontamination of these chemicals as required by AFR-161-22 and pertinent executive orders.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0412, RELATIONSHIP OF AIR POLLUTION TO HARDWOOD FORESTS OF THE NORTHEASTERN UNITED STATES
L.S. DOCHINGER, U.S. Dept. of Agriculture, N.E. Forest Experiment Station, *Delaware, Ohio* 43015 (FS-NE-2306)

OBJECTIVE: Define air pollution symptomatology and pollution interactions with disease incitants and evaluate efficiency of forest hardwood species in reducing air pollution.

APPROACH: Collect air samples by electrostatic and thermal precipitators, deposition, filtration, and grab samplings, and related methods; characterize atmospheric samples through analytical methods of gas chromatography, paper, column, and thin-layer chromatography, absorption spectroscopy instrumentation, and wet chemistry techniques; demonstrate pollution injury to forest hardwood species under controlled environmental growth chamber conditions, develop methodology for pathogenicity study for interactions of causal agents, biological systems, disease development, environment, and control; evaluate meterological instrumentation of wind recorders, temperature sensors, and barometric systems as they affect concentration and transport of pollutants in forests, determine physiological and biochemical mechanisms of hardwood trees which curtail air pollution.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

1.0413, SHADE TREE IMPROVEMENT THROUGH BREEDING AND SELECTION
A.M. TOWNSEND, U.S. Dept. of Agriculture, Shade & Ornamental Plants Lab., *Delaware, Ohio* 43015 (0995-10-07)

OBJECTIVE: Develop genetically superior shade and ornamental trees for urban plantings; obtain by selection and breeding horticulturally desirable elms resistant to the Dutch elm disease, phloem necrosis and other diseases; develop trees resistant to air and soil pollutants; determine efficiency of trees and shrubs in reducing air contaminants.

APPROACH: Incorporate disease and pollution resistance into selected shade tree species by hybridization with resistant exotic and native selections. Within important shade tree genera search for disease resistance and measure variation in sensitivity to specific pollutants. Using radioisotopes and other techniques determine uptake of gaseous and particulate contaminants by leaves.

PROGRESS:

SUPPORTED BY U.S. Dept. of Agriculture

1.0414, FOREST TREE IMPROVEMENT THROUGH SELECTION AND BREEDING

H.B. KRIEBEL, Ohio Agric. Res. & Dev. Center, *Wooster, Ohio* 44691 (OHO00229)

OBJECTIVE: Determine genetic diversity within selected forest tree species. Determine the physiology and evolution of growth and morphology. Develop hybrids by crossing selected races, utilizing provenance tests as parents. Stimulate early fruit production. Shorten testing by use of juvenile-mature correlations. Test seed sources of eastern white pine, European black pine, limber pine, Japanease larch, balsam fir, eastern cottonwood, red oak, sugar maple, black walnut and yellowpoplar.

APPROACH: Two replicates of cottonwood will be planted, also a black walnut seed source test; growth studied in the red oak test; and breeding planned for eastern white pine.

PROGRESS: Geographic sources of white pine in the southern Appalachians continued to have the fastest-growing trees in the provenance test. Form of the southernmost trees, however, is inferior for timber products or Christmas trees. Air pollution injury was present in trees of various sources, indicating that individual variation in susceptibility may be more important than racial variation. Cooperative red oak provenance tests in Ohio, Indiana, Michigan, Kansas, Nebraska and Iowa were measured, and reports sent to Ohio for overall analysis. Data have not yet been obtained from Illinois. Characters measured included fall foliage color, total height, diameter, crown width, and number of flushes during the growing season. Japanese larch showed good growth but no striking provenance differences; there was some injury by the larch casebearer. Variation was observed in Fusarium canker on Populus deltoides. No detailed analysis was made.

SUPPORTED BY U.S. Dept. of Agriculture

1.0415, PLANT GROWTH RESPONSES TO AIR POLLUTANTS

A. LIST, Drexel University, Graduate School, *Philadelphia, Pennsylvania* 19140

Growth in seedlings is monitored by two different methods capable of resolving small changes in growth rates on a continuous basis. Response to air pollutants will be interpreted in terms of growth effects, including short term transients. Oxygen consumption rates and transpiration rates are simultaneously monitored. 1) Streak photography of the 'Zea' primary root is coupled with oxygen polarography, while SO2 in air is passed over the coleoptiles, 2) Time lapse photography is done on 'Helianthus' seedlings for analysis of shoot extension and leaf expansion. This work is coupled with infra-red spectroscopy of water vapor content and leaf temperature measurements in an environmental chamber. Data from both methods is digitized on a high precision x-y coordinate plane digitizer, and processed by computer.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0416, GASES AND PARTICULATES IN POULTRY HOUSES

G.O. BRESSLER, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01778)

OBJECTIVE: Measure and establish levels of CO(2), CH(4), NH(3), and S gases and particulates in poultry houses according to management systems; determine levels of outside air contamination and develop methods of minimizing; correlate gas and particulate levels with physiological changes in chickens of various ages.

APPROACH: Gas and particulate levels will be measured by approved scientific methods in 2 large and 6 small poultry houses with various management systems, involving about 8000 chickens. Samplings will also be done on commercial poultry farms and surrounding environments. Chickens from control groups and groups exposed to various gaseous and particulate levels will be used for blood studies and histopathological examinations involving respiratory, cardiovascular systems and liver. Enzymatic changes in blood serum will be correlated to pathology in certain organs. Equipment and methods will be developed to minimize levels of gases and particulates in poultry houses and surrounding environments.

PROGRESS: Measurements of CO(2) and NH(3) were made in two poultry houses with 3000 leghorns each. Before pullets were housed the air inside the house contained 750 ppm of CO(2). In November the air contained 1575 ppm of CO(2) when a ventilation rate of about 2 cfm per bird was provided. When the ventilation rate was dropped to 4 cfm per bird in near zero temperature the CO(2) level rose to 2495 ppm. At this rate NH(3) was present at 10 to 15 ppm. Ten laying hens from a house with average dust and odor conditions (A) were compared with 10 hens from a house having increased dust and odor problems (B). The score of group A was 2.8 (excellent 0 4; poor 0 1), as compared to 2.5 from house B. Histopathologic lesions of mild to moderate pneumonitis, emphysema, edema plus peribronchial lymphatic hyperplasia appeared more pronounced in group B. Dust load in lungs of group B increased. Dust particles of 0.5 to 3 microns were incorporated in lymphatic tissue or in alveolar walls. The incidence of inactive or diseased ovaries, peritonitis or salpingitis also appeared greater in group B. Dust load and odorous gases can be correlated with increased pathology in the lungs and other organs and poorer carcass condition.

SUPPORTED BY U.S. Dept. of Agriculture

1.0417, BREEDING TREES RESISTANT TO AIR POLLUTANTS

H.D. GERHOLD, Penn. State University, School of Forestry, *University Park, Pennsylvania* 16802

Objectives: Adapt methods of testing the susceptibility of trees to air pollutant damage for use in a breeding system designed to produce resistant ornamental varieties.

Compare the early phases of several breeding systems as to their effectiveness in producing trees resistant to air pollutants.

Develop improved methods for the propagation of trees so that genetically superior individuals and varieties may be mass produced for immediate use.

Procedures: In a series of fumigation experiments the needles of pedigreed Scotch pine seedlings will be exposed to acute and chronic doses of ozone and sulfur dioxide . Optimum dates, concentrations, and durations will be sought for selecting resistant trees, evaluated by visual symptoms.

A modified diallel crossing program will be employed to obtain genetic information about the crossability, growth rate, and resistance to ozone and sulfur dioxide of about 25 geographically separated populations of Scotch pine and their F1 hybrids.

A series of experiments will explore the effects of important variables that influence the rooting of cuttings from young trees, including season, age of tree, branch position, and rooting bed environment.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0418, AIR POLLUTION PROBLEMS IN THE NORTHEAST

N.L. LACASSE, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01722)

OBJECTIVE: Determine the impact of present air contaminants on the agriculture of the northeast. Obtain information prerequisite for the development of air quality criteria as they relate to agriculture in the northeast.

1. AIR QUALITY

APPROACH: The first objective will be met by monitoring oxidant levels with an ozone meter. This information will be processed at Cornell University. The second objective will be met by determining the responses of plants to hydrogen chloride fumes, chlorine, and oxides of nitrogen. Plant response to long term, low level of fumigations will also be studied as well as the influence of environmental factors on plant response to these pollutants.

PROGRESS: Tomato plants and chrysanthemum rooted cuttings were exposed to HCl gas at concentrations ranging from 0.4 to 20 ppm for time period ranging from 1 to 40 hrs. Extracts of homogenized tissues were titrated and significant increases in chloride content were recorded in all portions of fumigated plants compared to control plants. Greatest increases in tomato occurred in secondary leaves not fully expanded. Lowest increases occurred in roots. Greatest increases in chrysanthemum occurred in immature upper leaves. Lowest increases occurred in roots. The predominant symptoms in acute damage to tomato and chrysanthemum are glazing of the lower surface and a bifacial bronzing of interveinal and marginal areas of leaves. Microscopic examination showed glazing to be caused by a collapse of lower epidermal cells and partial disorganization of spongy mesophyll of leaves. Bronzing results from further collapse of the spongy mesophyll, and in some cases, the palisade mesophyll and upper epidermis. (2) Oxidant levels were monitored from July 1 through Sept. 12. Oxidant concentration exceeded 5 pphm on 24 days. Number of hours over 5 pphm was 83.5. (3) Oxidant injury was again observed on Bel W-3 tobacco indicators.

SUPPORTED BY U.S. Dept. of Agriculture

1.0419, AIR POLLUTION EFFECTS

F.A. WOOD, Penn. State University, School of Agriculture, *University Park, Pennsylvania* 16802

Studies of the influence of leaf type, leaf age, length of exposure period and seed source on the susceptibility of Austrian and Scotch pines to 10 and 25 pphm ozone were completed. Similar studies utilizing three selections of Virginia pines have been completed but not analyzed. The exposure of white oak, sweet gum and white ash seedlings to 30 pphm PAN for periods up to 8 hours resulted in various types of symptoms on all three species. The typical glazing or silvering of the lower leaf surface was not observed. Histological examination of tissues indicated that the lower epidermis and the spongy mesophyll tissues were the first to be affected. During the coming year, we will continue to examine the relative sensitivity of various species of woody plants to ozone and PAN as well as expand our studies of the influence of environmental and phenological factors on plant sensitivity.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0420, EFFECT OF VARIOUS GASEOUS CONTAMINANTS OF THE ATMOSPHERE ON PLANT GROWTH AND BEHAVIOR

M.A. TIO, Univ. of Puerto Rico, Agricultural Experiment Sta., *Mayaguez, Puerto Rico* (PR00220)

OBJECTIVE: Obtain specific information on effects of some gases such as sulphur dioxide, hydrogen sulphide, carbon monoxide, phthalic acid, ozone, carbon disulphide, fluorides and other gases, on several plant species of economic importance in Puerto Rico.

APPROACH: A comprehensive survey of the levels of contamination of the atmosphere of Puerto Rico will be carried out. Plants of economic importance will be fumigated in closed chambers, both in the laboratory and in the field to observe effects on: respiration of plants, photosynthetic rate, assimilation of nutrients, conditions of chloroplasts and stomata, morphogenetic changes and reproduction. The effects of gases on the roots and some enzymatic systems of the plants will also be studied. The tolerance of each species of plants of economic importance to contaminants will be determined. The effects of atmospheric pollutants on growth, yield, quality of crop, and reproduction will be studied in the field.

PROGRESS: A survey is in progress to determine the areas affected by contaminants emitted by different industries. Affected plant material is being collected and photographed. The managements of several concerns have been interviewed with the purpose of gaining information on concentration and site of origin of specific industrial effluents.

SUPPORTED BY U.S. Dept. of Agriculture

1.0421, THE EFFECTS OF ATMOSPHERIC POLLUTION ON EPIPHYTES

G.R. HOFFMAN, Univ. of South Dakota, Graduate School, *Vermillion, South Dakota* 57069

In Europe Lichens and bryophytes on tree bark have shown to be sensitive indicators of air pollution. In the U. S. leading lichenologists propose the same to be true here, but to date very little actual study has been directed toward the problem. I have previously studied the ecological distribution of epiphytic cryptogams on the common Douglas fir in a broad geographic transect extending from the western edge of Washington state to the middle of Montana. All sites were picked in locations where atmospheric pollution is not significantly noticeable. We are now extending our field studies to include within this broad geographic transect those fairly isolated pollution sources such as smelters, paper pulp mills, lumbering operations to determine the effects of such pollution on epiphytic cryptogams and to map the distributions of many such cryptogams in polluted areas.

The purpose is to determine the usefulness of these epiphytes as indicators of levels of air pollution.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0422, ECOLOGICAL METEOROLOGY STUDIES: A PINE PLANTATION

F.A. GIFFORD, U.S. Dept. of Commerce, Air Reso. Atm. Turb. Dif. Lab., *Oak Ridge, Tennessee* 37830 (AT(40-1))

The objective of the study is to determine the wind and turbulence characteristics within and above a loblolly pine plantation, to relate these characteristics to the structure of the stand, and to investigate the coupling between wind within and above the plantation. Information gained in this study will be of value to air pollution meteorology, ecology, and forestry. This study is included in the deciduous forest biome project of the IBP. Mean wind and temperature profiles will be measured on a 120 ft. tower using sensitive cup anemometers and thermistors respectively. Turbulent velocities are to be measured with hot wire anemometers. Temperature fluctuations are to be measured with a thermistor of kw response time (less than 1 sec.). Profile measuremefts will be used to characterize meteorologic conditions during measurement of turbulence parameters. Turbulence parameters will be used to calculate turbulent intensities, shear stress, turbulent transfer coefficients, energy spectra, and eddy dissipation rates. The test object is a pine plantation located at the ORNL Post Attack Ecology Site. The plantation is aproximately 25 years old and trees are 40-45 feet tall. The plantation is fairly uniform within 400 feet of tower in the sector south of the tower from east to northwest.

Results: Site selection and instrument acquisition completed. Measurements to begin upon completion of power line to tower site.

SUPPORTED BY U.S. Atomic Energy Commission

1.0423, SELECTED AIR POLLUTANTS AFFECTING PLANTS AND HEALTH

H.G. APPLEGATE, Texas A & M University System, Agricultural Experiment Sta., *College Station, Texas* 77843 (TEX01236)

OBJECTIVE: Make quantitative and qualitative measurements of air pollutants at selected sites in Texas; develop or adapt analytical methods and techniques sensitive to the lower limits known to affect vegetation, animals, and man, for sampling and measuring selected air pollutants in Texas; experimentally investigate in the laboratory those physiological responses of organisms to air pollutants observed in the field.

PROGRESS: Particulate emissions from peanut shelling plants were monitored. In cooperation with environmental engineering, recommendations were made for installing of equipment to bring the plants into compliance with regulations of the Texas Air Quality Board.

SUPPORTED BY Texas State Government - Austin

1.0424, EARLY DIAGNOSIS OF POLLUTION-INDUCED PLANT DAMAGE
J.R. ROWLANDS, Southwest Research Institute, *San Antonio, Texas* 78228

The overall objective of the proposed research is the detection and interpretation of initial structural changes produced in plant membranes and photo-synthetic systems by air pollutants. Experimental plants, principally tobacco and spinach, will be grown in a greenhouse, exposed to specific air pollutants in an exposure chamber, and the leaves will be used to obtain chloroplasts, cell wall fragments, and subchloroplast fractions. These various preparations will be studied by means of electron spin resonance (ESR), circular dichroism (CD), ESR spin labeling, nuclear magnetic resonance (NMR), and fluorescence/phosphorescence and optical spectroscopy. In addition to the membranes, the chloroplast and subchloroplast fragments will be compared as to ability to produce free radicals I and II of photosynthesis and the rates of production of these radicals.

1.0426, PLANT DISEASE SURVEY
O.S. CANNON, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00034)

OBJECTIVE: Determine the presence, distribution and economic significance of diseases of major crops in Utah, including those caused by air pollutants. Also determine whether the organism which causes fire blight of apples and pears overwinters elsewhere than in cankers of diseased trees.

APPROACH: Inspect growing crops in Utah for diseases and develop new methods of control if established control methods are not giving satisfactory results.

PROGRESS: Again in 1969 fireblight (caused by Erwinia amylovora) was less prevalent than in 1967 when it caused heavy losses in both pears and apples. This bears out the observations previously made that weather conditions and their effects on hosts and the fireblight organism are more important in the development of fireblight than the number of fireblight cankers left on trees within an orchard. A graduate student, Terry Miller, developed a rapid serological bean blight detection procedure, and showed that it is much more reliable in detecting bean blight in a field than field observation. Heavy snowfall in the late winter was responsible for development of unusual amounts of snow-mold in winter wheat in northern Utah. Dwarf bunt also caused heavy losses in some wheat fields. In most areas of the state there were fewer leaf and fruit diseases than in the preceding year. There was marked SO(2) injury to alfalfa near Magna in August.

SUPPORTED BY Utah State Government

1.0427, HF-AIR POLLUTION AND INTERMEDIARY METABOLISM
G.W. MILLER, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00646)

OBJECTIVE: Determine the mechanism of fluoride enhanced respiration. Determine the mechanism of fluoride induced chlorosis and necrosis. Investigate the synthesis and importance of fluoro-carbon compounds in plants.

APPROACH: Examine the structural integrity, oxygen uptake and phosphorylation of mitochondria in relation to membrane stability as influenced by calcium and fluoride. Determine any change in adenosinediphosphate (ADP)/adenosinetriphosphate (ATP) ratios in tissue from plants exposed to fluoride or calcium deficiency. Determine increased activity of oxidative enzymes in vivo and determine if acceleration can be attributed to a source of increased substrate. Examine the fluoride induced deficiency of chlorophyll with respect to chlorophylase activity and the integrity of the chloroplast membrane. Differentiate and determine the nature of the increased protein in fluoride injured tissues. Determine the metabolic reactions resulting in accumulation of pipecolic acid in fluoride injured tissue and its relation to necrosis of cells. Establish conditions required and species capable of synthesizing fluoro-carbon compounds. Determine the carbon compound capable of being fluorinated and the mechanism of the reaction. Determine the effects of fluoro-organic acids on plant metabolism.

PROGRESS: Study results of fluoride mitochondria treatment indicate fluoride effects resulting in stimulated respiration, decreased phosphorylation and increase ATPase activity may be due to indirect effect of fluoride on mitochondrial membrane permeability or transitory direct effect of fluoride on mitochondrial permeability. Fluoride treated mitochondria respond as do those from tissue with long exposure to fluoride with inhibition of dehydrogenase enzymes and ATPase, and a reduced respiration. Wheat root injury may be caused by available calcium depletion which may alter cell permeability. Electron micrographs of fluoride fumigated tissue revealed swollen mitochondria with obliterated cristae and electron dense particle deposition. Methods were developed for gas chromatographic separation and identification of fluoroacetate and fluorocitrate methyl esters. This toxic compound presence was detected in fluoride fumigated soybean and alfalfa and in crested wheatgrass exposed to fluoride pollution.

SUPPORTED BY Utah State Government

1.0428, FLUOROSIS IN PLANTS AND ANIMALS
J.L. SHUPE, Utah State University, Agricultural Experiment Sta., *Logan, Utah* 84321 (UTA00364)

OBJECTIVE: Determine the distribution and degree of fluorosis in animals. Conduct necropsies and pathologic studies on animals with varying degrees of clinical fluorosis. Determine and evaluate the reabsorption of fluorine from bone following cessation of excessive ingestion of fluorine. Study the breaking strength of normal and osteofluorotic bone.

APPROACH: Field surveys will be made to determine the degree and distribution of fluorosis in animals. When deemed worthwhile or necessary, animals evidencing varying degrees of clinical fluorosis will be necropsied. Clinical and detailed pathologic comparisons will be made between animals that are maintained on an excessive fluoride ration and those that have been maintained on a normal (low fluoride) ration after having ingested excessive fluorides long enough to induce characteristic dental and osteofluorotic lesions. Bones from selected cases will be subjected to torsion, bending, stretching, and compression tests to determine the breaking strength of bone as related to the degree of osteofluorosis.

PROGRESS: Horses, sheep, dairy and beef animals were clinically examined to determine and evaluate distribution and degree of flourine toxicosis in livestock. Necropsy studies were conducted on sheep, dogs, bison, dairy and beef animals. Livestock in Utah County still evidence varying degrees of fluorosis. Effects on animals of a particulate air pollutant called 'kish' is not known. The amount of this material on the vegetation and farms is related to distance and direction from the industrial operation at Geneva. Studies are in progress to determine the relationship of osteofluorosis to bone density and the breaking strength of bone, the effects of excessive intermittent fluoride ingestion, and bone enzyme activity as related to the degree of osteofluorosis. Many factors can and do influence the degree of fluorosis in animals. We have been unable to relate ambient air fluoride levels to the degree of fluorosis in livestock. In many cases vegetative fluoride levels cannot be correlated with the degree of fluorosis in livestock, however, in some cases vegetative fluoride levels can be correlated with the degree of fluorosis. Information developed here is used to help establish state and national air standards and laws.

1. AIR QUALITY

SUPPORTED BY Utah State Government

1.0429, IMPACT OF AIR POLLUTANTS ON ECOSYSTEMS
K.T. HARPER, Univ. of Utah, School of Letters, *Salt Lake City, Utah* 84112

The primary research objective of this study is to determine the impact which air pollutants have now or may have in the future on four natural ecosystems important to the Salt Lake Valley for watershed protection and/or recreation. Current levels of photochemical pollutants in air sheds over the selected ecosystems will be monitored by means of sensitive plant indicators and standard analytical devices. Effects of pollutants on growth and reproductive processes of dominant plants of each ecosystem will be determined from fumigation trials conducted under growth-chamber, greenhouse and field conditions.

Dominant plants (those plants that would most alter the ecosystem if they were eliminated) will be identified by means of modern, quantitative ecological measurements of many stands in each of the ecosystems selected. Environmental data will be taken at each stand to determine the range of site variation within each ecosystem and response of individual species to that variation. Permanent study plots encompassing the range in variation in each ecosystem will be selected for further observation and study. Changes in community composition and successional trends following field fumigations will be documented.

Fumigation studies have demonstrated the extreme sensitivity of representative native species. Whose growth was impaired at ambient peak ozone concentrations of 10 to 15 pphm. The reproduction potential of these species has been studied but data have not yet been analyzed.

1.0430, EFFECTS AND FATE OF AIR POLLUTANTS
A.C. HILL, Univ. of Utah, Graduate School, *Salt Lake City, Utah* 84112

The first objective is to determine the effects of the major phytotoxic air pollutants, alone and in combination, on plant growth suppression. Inhibition of the rate of apparent photosynthesis will be used as a measure of growth suppression. The experiments will be conducted in environmental chambers that were designed and built specifically for the project. Temperature, light, relative humidity, wind velocity, and pollutant concentration will be controlled, and transpiration, stomatal opening, and pollutant uptake rate will be measured.

The second objective is to determine the role of vegetation as a sink for gaseous air pollutants. The uptake rates of the major pollutants (SO2, HF, O3, PAN, NO, NO2, CO, etc.) will be measured using typical vegetation canopies and environmental conditions. Measurements will be made in our environmental chambers. The effects of factors such as plant species, height and density of the vegetation cover, wind velocity, stomatal opening, light intensity, temperature, and relative humidity will be measured. Field studies will be conducted and compared with the measurements made in the chambers.

1.0431, EFFECTS OF FLUORIDE ON PHOSPHORUS METABOLISM OF PLANTS
M.R. PACK, Washington State University, School of Engineering, *Pullman, Washington* 99163

Studies of the response of plant respiration to fluoride have given somewhat conflicting results, and little is known about the relationship of the respiration response to effects of fluoride on other aspects of plant metabolism. The concentrations of various acid-soluble phosphorus compounds in plant tissues have been affected by fluoride treatments, but the significance of this response is uncertain.

In an effort to resolve some of these uncertainties, it is proposed to investigate the relationship between the response of plant respiration to fluoride and effects of the fluoride on phosphorus metabo...m by making concurrent, time-course measurements of oxygen uptake and acid-soluble phosphorus compounds in the leaves of bean seedlings exposed to hydrogen fluoride. Enzymes that appear to be affected then will be studied more directly to evaluate their response to fluoride.

If effects of fluoride on respiration can be related to differences in the pools of certain phosphorylated intermediates and these in turn can be linked to fluoride inhibition of specific enzymes, considerable progress will have been made in understanding the mechanisms of effects of atmospheric fluoride on plants, and some of the apparent inconsistencies of previous findings may be resolved. Such information is needed for accurate appraisal of the potential ramifications of fluoride pollution injury to vegetation.

Preliminary results of an experiment with bean plants exposed to hydrogen fluoride at 4.7 micrograms F/m3 have failed as yet to show any effects of the fluoride treatment.

1.0432, BACKGROUND AEROSOL LIGHT SCATTERING
R.J. CHARLSON, Univ. of Washington, Graduate School, *Seattle, Washington* 98105

The object of this research is to determine the relationship of the backscattered aerosol light component to the total light extinction, and to establish background levels of both components. This provides fundamental measurements on the aerosol content of our atmosphere before man's activities obscure the natural background.

The measurements will be taken with a specially adapted integrating nephelometer. The resulting information on the concentration and backscattering properties of the aerosol in the earth's atmosphere can be used to evaluate the role of the atmospheric aerosol in determining the albedo of our planet's atmosphere and its consequent effect upon the heat balance.

SUPPORTED BY U.S. National Science Foundation

1.0433, EFFECTS OF AIR POLLUTANTS ON AIRBORNE MICROBES
B. LIGHTHART, Univ. of Washington, School of Engineering, *Seattle, Washington* 98105

It is the purpose of this project to initiate a pilot study to screen five common urban air polluting gases, i.e., ozone, carbon monoxide, nitrogen dioxide, SO2 and formaldehyde, for their antibacterial activity on three distinctly different bacteria. The antibacterial activity of the gases will be measured in terms of changes in bacterial survival-time relationships. The organisms used will represent a broad range of bacterial sensitivity to toxic agents.

The screening experiments will be carried on in a pre-conditioned atmosphere enclosed in a rotating drum-type test chamber. Pre- conditioning includes controlled temperature, relative humidity (RH) and pollutant gas concentration. The survival of the bacteria in an aerosol injected into the test atmosphere will be monitored as a function of time. Cell survival in each of the gases will be tested at six relative humidities. (Several RH levels have been used because it is anticipated that RH will greatly temper the effects of the pollutants on survival.)

Data generated from the thirty-six survival experiments will be analyzed to elucidate the effects of pollutants on the aerial survival of the test cultures as a function of time, relative humidity and cell type. An attempt will be made to generate a mathematical model that will approximate some of the test parameters.

1.0434, INTERDISCIPLINARY RESEARCH PROGRAM IN CLIMATOLOGY
R.A. BRYSON, Univ. of Wisconsin, Graduate School, *Madison, Wisconsin*

The objective of the program is a quantitative understanding of the world patterns of climate, its causes and mechanisms, its evolution in time and the impact of climate on patterns and changes of ecological systems.

Special emphasis will be placed on the following areas of work: (1) a study of naturally bonded, internally homogeneous regions of atmospheric parameter complexes; (2) a systematic in-

vestigation of spatial and temporal covariance structure of meteorological variables; (3) a study of the distribution and climatic effect of atmospheric particulates and their role in climatic modification; (4) a study of climatonomic relations as inputs for climatic modelling and as possible mechanisms for climatic modifications; (5) development or adaptation of numerical models of climate for testing theories of climatic change; (6) development of quantitative methods for gathering and interpretation of data on past climates and the reconstruction of past climatic patterns; (7) detailed studies of climatic variability and climatic change; and (8) exploration of quantitative relationships of macroclimates, microclimates and biota including man and the ecological effects of climatic change or modification

SUPPORTED BY U.S. National Science Foundation

1.0435, VEGETABLE CROPS IMPROVEMENT THROUGH BREEDING

W.H. GABELMAN, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01025)

OBJECTIVE: Improve certain vegetable crops via genetic studies and breeding procedures.

APPROACH: Isolate heritable controls of significant plant responses and composition in vegetable crops, especially carrot, table beet, onion and bean. Determine genetic basis. Improve varieties for adaptation and nutritional value through plant breeding techniques.

PROGRESS: Inbred onions with multiple resistance to ozone, fusarium and pink root have been developed. As soon as the procedures for handling the release of inbred materials under the proposed Plant Protection Act are clarified, these will be made available to the public. Inbred lines with high color and good seed production potential and excellent combining ability have been developed in carrots. These inbreds also will be released as soon as the Plant Protection Act is clarified. Inbred liner of snapbeans have been isolated which appear to be efficient for the production of dry matter under very low levels of phosphorus as opposed to other inbreds which are very inefficient. Within each group of efficient and inefficient inbreds we also have sub- groups which either respond to added phosphorus or do not respond. This work is being continued in the Biotron to determine the heritability of these two responses.

SUPPORTED BY U.S. Dept. of Agriculture

1.0436, AIRSACCULITIS OF TURKEYS

R.P. HANSON, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01181)

OBJECTIVE: Determine environmental effects on airsacculitis.

APPROACH: Environmental variables - ambient temperature and humidity, light, feed, water, ventilation, litter condition, content of air is continuously monitored in large part by automatic recording equipment. Activity and health of turkeys is recorded in part by automatic equipment and is also a subject of sampling technics. Special attention has been given to airborne pathogens and to air pollutants.

SUPPORTED BY Wisconsin State Government - Madison

1.0437, AIR POLLUTION DAMAGE IN WHITE PINE

G.R. STAIRS, Univ. of Wisconsin, Agricultural Experiment Sta., *Madison, Wisconsin* (WIS01595)

OBJECTIVE: The objectives of the proposed research are to investigate: (1) the genetic control of resistance to atmospheric ozone and other oxidants in white pine; (2) the biochemical basis for this resistance; and (3) the areal extent of damage based on evaluations made in (1) and (2) above.

APPROACH: The following approach will be utilized: conduct a repeatability study utilizing clonally replicated material of selected resistant and susceptible white pine under controlled fumigation conditions in greenhouse chambers. Determine which, if any, of the following classes of plant chemical compounds are of importance in the mechanism of resistance: terpenes and essential leaf oils, carbohydrates, including sugars and starch, lipids, phenolic compounds, polyphenolic derivatives and free amino acids, and define suitable protein (enzyme) extraction techniques for leaf tissue of white pine, and by disc electrophoresis determine if differences exist in protein (enzyme) composition, production or activity between resistant and susceptible material before or after exposure to atmospheric oxidant (ozone).

PROGRESS: Field selections of resistant and susceptible genotypes were completed; each selection was clonally propagated by grafting to allow control-chamber repeatability testing. Chamber tests with ozone levels to 15 parts per hundred million (pphm) indicated that ozone damage was not the significant factor contributing to the air pollution damage observed under ambient conditions. Repeatability of response for pollution-sensitive material was high (0.90) and an excellent correlation was observed between field and greenhouse grown materials. Biochemical evaluations for phenolic content of the foliage by two- dimensional TLC indicated quantitative and qualitative differences between the two resistance classes but additional work is need to relate the physiological significance of these results.

SUPPORTED BY U.S. Dept. of Agriculture

1.0438, INADVERTENT WEATHER MODIFICATION BY URBAN POLLUTION

D.L. VEAL, Univ. of Wyoming, School of Engineering, *Laramie, Wyoming* 82070

Inadvertent weather modification has been shown to exist climatologically and some possible physical links have been indicated. However, no comprehensive investigation has been undertaken to describe and indicate the various physical processes that lead to the observed effects. The objectives of this proposed study therefore, are: A. Meso-scale circulation features: 1. Observe and analyze the kinematics of the meso-scale motion over an urbanized area; and 2. Numerically model the meso-scale motions associated with an urban atmosphere. B. Nucleus Concentrations: 1. Establish quantitatively the production of cloud, Aitken and ice nuclei by an urban environment. C. Cloud and Precipitation Processes: 1. Investigate the transfer processes of the urban aerosol to the cloud particles; 2. Determine the effects of urban produced cloud nuclei on the structure of the cloud; 3. Investigate the coalescence mechanism of precipitation associated with the polluted conditions; 4. Investigate the role of ice nuclei; and 5. Investigate the evolution of the resulting cloud particles into precipitation.

D. ECONOMIC ASPECTS

Includes Losses From Pollution Damage and Costs of Control Programs.

1.0439, SYSTEMS EVALUATION OF REFUSE AS A LOW SULFUR FUEL

S.B. KILNER, Aerojet General Corporation, *Los Angeles, California* 90007

Objective: Complete report on feasibility of refuse firing for power generation, preliminary engineering of preferred modes, potential pollutant reduction resulting, and recommended R&D plans.

Description: The study will assess the present and future potential for reducing sulfur oxide and particulate emissions and the costs of refuse disposal by integrated power generation and refuse disposal facilities in metropolitan areas. Estimates of present and projected quantities and composition of refuse for the U.S. and six metropolitan areas will be made and combustion and pollution-forming properties with proportions of fossil fuels will be determined. Technology and economics of present boiler and power plant practice, combined firing as practiced in Europe, and preferred configurations for U.S. application will be assessed. Economic and political feasibility and potential pollutant reduction will be estimated and projected through year 2000. Five-year R&D plans for developing promising systems and components will be detailed.

1. AIR QUALITY

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0440, TECHNICAL AND ECONOMIC FEASIBILITY OF OIL-FIRED COGAS POWER STATIONS
A.J. GIRAMONTI, United Aircraft Corporation, *Hartford, Connecticut*

The purpose of the study is to investigate the technical and economic feasibility of using advanced power systems to generate electricity from heavy residual fuel oil at increased efficiency and without causing atmospheric or water thermal pollution. The advanced power system would involve gasification and purification of the oil to produce a clean fuel gas which would be burned in a nonpolluting COGAS or combined gas and steam turbine power system. Primary emphasis during the program will be placed on selection of the oil gasification process which offers the potential for producing lowest-cost nonpolluting gaseous fuel to the power system, identification of the COGAS system configuration and operating characteristics which offer the potential for producing lowest-cost electric power, and preparation of owning and operating cost estimates for prospective oil-fired COGAS power stations.

SUPPORTED BY Connecticut State Government

1.0441, ECONOMICS OF ENVIRONMENTAL EFFECTS ON SEASONAL HOMES
G.L. COLE, Univ. of Delaware, Agricultural Experiment Sta., *Newark, Delaware* 19711 (DEL00152-AE)

OBJECTIVE: Determine environmental situations associated with seasonal homes. Evaluate social and private costs and benefits of identified environmental situations. Assess current and alternative institutional arrangements. Determine potential market for seasonal homes in the Northeast.

APPROACH: A representative sample of environmental situations in seashore communities will be selected and interviews will be conducted with health officials and seasonal home owners to identify positive and negative effects of seasonal home communities. Secondary data will be used to assess non-monetary costs and benefits associated with seasonal home development, i.e., pollution, reduction of access, etc. Alternative institutional arrangements will be evaluated after assessing the current setting.

PROGRESS: Delaware's contribution to the regional effort will focus around seasonal home communities on or near the Atlantic Ocean and nearby bays. The objectives are: (1) to determine the environmental situations (positive and negative) associated with seasonal homes and to analyze the attitudes, interests and goals of people for a quality seasonal home environment, and (2) to evaluate the social and private costs and benefits of identified environmental situations at both the regional and national levels. Work is underway to develop a standard methodology and questionnaires for the region to investigate the attitudes of seasonal home occupants and developers, permanent residents and public officials concerning environmental quality in the communities. Scientists from such disciplines as sanitary and civil engineering, landscape architecture, geography and planning will be consulted in order to identify important variables to be included in the study. Field work will begin during the summer of 1970.

1.0442, MEASURING PERFORMANCE IN PUBLIC PROGRAMS
UNKNOWN, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

Progress 7/68 through 6/69: Definitions of and distinctions between the benefits and efficiency of public programs have been established. Program inputs, outputs and benefits have been defined rigorously as a basis for data collection and analysis. An analytical procedure is being developed and tested empirically with case studies and aggregate statistical data for science and technology programs. Data on the output and input of selected science programs have been compiled in a time series to indicate trends and relationships. Case studies are being conducted to evaluate the economic effects of public programs to improve physical measurements. Questions here are: What is the economic role of measurements; What is the effect of improving measurement; Who should decide upon the quality of measurement and pay for its attainment? A model has been developed to measure the economic value of public programs to reduce hazards (eg., fire, earthquake, crime, pollution) and is being tested empirically for fire research programs.

SUPPORTED BY U.S. Dept. of Commerce - N.B.S.

1.0443, ECONOMIC EVALUATION OF ALTERNATIVE POLICIES FOR AIR RESOURCE MANAGEMENT
A. TELLER, Univ. of Illinois, Graduate School, *Urbana, Illinois* 61801

The Specific Aims and Expected Results - The specific aim of the study is to develop a computer model for the analysis of air pollution policy alternatives and apply it to the Chicago metropolitan area. This model would incorporate information on sources of emissions (both stationary and mobile), costs of control, atmospheric conditions, and benefits from pollution control. In addition, the investigators will make detailed studies of control costs and benefits. The project would result in two reports: (1) a monograph relating scientific findings and spelling out their policy implications, and (2) a manual-type report setting out the technical details of the model so that it will be available to other metropolitan areas.

SUPPORTED BY Resources for Future Inc. - Wash., D.C.

1.0444, OPTIMAL CONTROL OF POLLUTION DISTRIBUTION
F.A. TILLMAN, Kansas State University, School of Engineering, *Manhattan, Kansas* 66502

The purpose of the research is to determine the feasibility of building a linear programming model to solve the pollution allocation problem.

This problem can be viewed as a resource allocation problem. The resource that is to be allocated is the amount of pollution that can be tolerated in each region so that the overall criteria is optimized. One aspect of the problem will be to investigate the effect of reducing the pollution in the area by considering the cost of reducing pollution to each of the contributing sources. This approach could be the basis of a tax program in which the contributing sources would be taxed on an equitable basis and the funds spent where the greatest benefits could be made. The essence of the research will be to determine if the important variables can be defined and if enough detail can be built into the model to represent the problem.

If such a model is built, these problems could be solved for each community and an overall plan developed so that a realistic policy is determined for zoning and controlling industrial parks. With these models a dynamic policy could be maintained. Thus, as critical pollution conditions exist schedules would be set up for allowing the polluting sources to operate at according to fixed schedules during the day and week. Every effort will be made to incorporate in the present techniques and information generated by Prof. Takamatsu's group. To start this exploratory investigation, their data will be used to test the proposed techniques.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0445, THE SOCIAL AND ECONOMIC IMPACT OF THE SUBSTITUTION OF LOW SULFUR COAL FOR HIGH SULFUR COAL - A PILOT STUDY OF MONONGALIA COUNTY, W. VA.
D.M. BROWN, Northeastern University, School of Liberal Arts, *Boston, Massachusetts* 02115

The purpose of this study was to show how a detailed impact analysis can be made with secondary data. A six-equation econometric model of the coal sector and county economy were constructed and alternative impacts of proposed air pollution legislation were found. The major conclusion of the study was that the coal industries will not have to shut down if strong anti-pollution legislation is passed.

SUPPORTED BY No Formal Support Reported

1.0446, AN EVALUATION OF FREE TRANSIT SERVICE
UNKNOWN, Charles River Associates Inc., *Cambridge, Massachusetts* 02138 (000427)

This study will examine the economic, social, technological, and financial factors in an evaluation of free transit in metropolitan areas as a policy alternative. The study will include consideration of such diverse factors as: the influence of cost of transportation and quality of service as an incentive to its use, implicit income transfers, changes in transportation cost in money, time and service, congestion, transportation investment, transportation facilities, air pollution, land use, financial instruments, and effect of various levels of subsidy.

The study is based on economic analysis for its findings. It relies heavily on the use of a new and improved method for predicting traffic volumes over a variety of urban transportation systems. In this method, volumes are a function of both travel times and money costs of competing systems. Findings are based on a case study of the Boston area, and on an extension of case study results to the national level.

Because of the limited scope of the contract, the study does not take into account long range benefits which may or may not accrue from the use of free transit. The study does provide estimates of short run shifts in the demand for urban passenger transportation by various modes. It finds that the short run cost of free transit to the public would be about $2 billion per year. It analyzes the impact of free transit in terms of such issues as accessibility of jobs to inner city residents, revitalizing the downtown and reducing highway congestion, air pollution and parking problems. It discusses administrative and income redistributional considerations and it identifies research needs.

1.0447, OPTIMIZATION STUDIES IN INDUSTRIAL POLLUTION CONTROL
J.L. GADDY, Univ. of Missouri, School of Engineering, *Rolla, Missouri* 65401

A specific pollution control problem in a chemical plant may be solved by the installation of a particular type of equipment to remove the pollutants from the effluent air or water streams. There may be several types of equipment that would accomplish the required removal. The pollutants may also be eliminated at the source, either in the raw materials or at the point where they are produced or recovered in the process. Therefore, there are many solutions to each pollution problem and, consequently, there is a best or optimum solution which will maximize the economy.

The purpose of this project is to develop a computer system to optimize industrial pollution problems. This will be done by modifying CHESS (Chemical Engineering Systems Simulator), a computer simulation program for modeling chemical processes to include pollution control modules; and the development of a mechanism for optimization of the possible pollution control methods. In addition to the optimum pollution control scheme, the program will define the investment and increased operating cost required to implement each scheme.

SUPPORTED BY University of Missouri

1.0448, NATIONAL ENERGY NEEDS AND ENVIRONMENTAL QUALITY
C.L. COMAR, State University of New York, School of Veterinary Medicine, *Ithaca, New York* 14850

The objective of this project is to systematically evaluate the options, costs, environmental consequences, and possible constraints on meeting the energy requirements of our expanding economy. Special consideration will be given to the biological costs of the various alternatives.

Over the next few decades, considerable expansion of production facilities will be needed in order to supply the energy requirements of the nation. One of the most urgent problems of the 1970's is to determine just how this necessary expansion can take place without resulting in widespread environmental damage and hazards. We are already witnessing severe conflicts between proposals for added capacity and the desire for no further deterioration of the environment. Decisions must be made on how and where facilities can be constructed in order to provide a reliable supply of power on schedule, at a reasonable cost, and with a minimum of harm to man, pollution of air or water, and despoilation of land.

The project will emphasize three phases: (1) projection of energy requirements particularly with regard to socio-economic factors and analysis of the modes of meeting these requirements; (2) comparisons of the total biological costs of the various modes of meeting energy needs as well as the biological costs of not providing additional energy; (3) analysis of the interdisciplinary procedures and organization utilized in studies (1) and (2) above.

SUPPORTED BY U.S. National Science Foundation

1.0449, HIGH SULFUR COMBUSTOR STUDY
J. BELDING, Chemical Construction Co., *New York, New York*

Objective: To determine the technical and economic feasibility of the high sulfur combustor concept.

Description: A promising technique for the control of sulfur dioxide pollution from coal-burning installations is the removal of pyritic sulfur from the coal prior to combustion. The economics of deep cleaning have prevented widespread use of the technology for cleaning so- called 'steam coals.' Significant amounts of carbon are lost in the reject material from the deep cleaning of coal. A potential solution to the problem of carbon loss is the utilization of this high-ash, high- sulfur, carbon-bearing reject material in a special combustor. The reject material should have sufficient heat value for steam raising, and the flue gas resulting from the combustion of the reject material should contain a relatively highly concentration of sulfur compounds. Recovery of these compounds by flue gas processing would provide a useful and salable product. Feasibility studies conducted previously by NAPCA have indicated that the combination of a high-sulfur combustor and a process to recover sulfur as sulfuric acid from the flue gas may provide the economic incentive for deep cleaning of steam coals. In addition, processes which would produce liquid SO2 or elemental sulfur are promising alternates, as well. The purpose of the high-sulfur combustor study is the selection, design, and evaluation of the combustor and sulfur recovery process with the greatest potential for economically utilizing high-ash, high-sulfur coal reject material produced by the deep cleaning.

1.0450, AN EMISSION AND CONTROL COST STUDY OF THE REACTIVE METALS INDUSTRY
F.L. BUNYARD, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop relaible, comprehensive information on the present and future costs of controlling air pollutant emissions for the reactive metals industry.

Approach: Current expenditures by the industry for air pollution control will be assessed on a national and regional basis. Provision will be made for estimating the future control costs required to meet specific emission standards. Particulates are the major emissions to be considered in this study. The study will be done jointly by NAPCA and MCA.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0451, DEVELOPMENT OF SULFUR OXIDE CONTROL COSTS FOR COMBUSTION SOURCES
F.L. BUNYARD, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop reliable control cost information for the control of sulfur oxides from combustion sources.

1. AIR QUALITY

Approach: Published information from many groups will be compiled and evaluated. Principal sources of information will be the Division of Process Control Engineering and Fuels Policy Section. Extensive baseline data will be obtained by means of the FPC Form 67 which will provide data annually on fuel quantity and quality burned by public utility companies.

Goal: The first phase of the study will be one year and be concerned with developing the baseline data. The study will be updated annually as new information becomes available.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0452, REGIONAL CONTROL COST STUDY IN BUFFALO

F.A. COLLINS, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To provide control cost estimates to be used in conducting a cost benefit analysis for the Buffalo Air Quality Control Region.

Approach: The method to be followed will be similar to that used in Philadelphia. Particulate and sulfur dioxide emissions from stationary sources will be considered.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0453, REGIONAL CONTROL COST STUDY IN PHILADELPHIA

F.A. COLLINS, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To make control cost estimates for the Philadelphia Air Quality Control Regions.

Approach: Estimates will be made of the costs to control particulate and sulfur oxides to achieve varying air quality levels. Much of the task will involve verification of the cost estimates generated by the Implementation Planning Program developed by TRW.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0454, ECE QUESTIONNAIRE ANALYSIS AND STUDY PROPOSAL

R.C. DICKERSON, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Information on economic studies related to air pollution will be collected and exhanged on an international scale.

Approach: Questionnaires have been prepared and several governments of the world have been asked to respond. Information gathered from the questionnaire will be used to evaluate past and present work to determine future needs.

Goal: The evaluation should be completed within one year.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0455, AN EMISSION AND CONTROL STUDY OF THE RENDERING INDUSTRY

G.F. EVANS, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop reliable, comprehensive information on the present and future costs of controlling air pollutant emissions for the Rendering Industry.

Approach: Current expenditures by the industry for air pollution control will be assessed on a national and regional basis. Provision will be made for estimating the future control costs required to meet specific (but as yet undetermined) emission standards. Odors are the principle pollutant to be considered in this study. A special aspect of this study will be to estimate what the impact of air pollution control expenditures will be to this industry. The information will be obtained by use of a questionnaire generated by NAPCA. DAQED will obtain information with respect to the emissions (type and quantities) of this industry.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0456, ECONOMIC IMPACT OF AIR POLLUTION IN THE SAN BERNARDINO FOREST AREA

D.G. GILLETTE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Assess the economic effects of forest destruction by photochemical smog on land use, property values, recreational and aesthetic values, and the general economic activity in the San Bernardino Forest area.

Approach: During FY 71 a preliminary investigation will be conducted to determine the availability and usefulness of various sources of data to assess the economic effects of air pollution on the San Bernardino forests. Such an assessment will necessarily include an evaluation of the impact of forest destruction on the Los Angeles watershed, recreation and timber values. Among the type of data to be collected will be sales data on timber and land, fire insurance costs and cost of forest fire potection to the U.S. Government, cost of cleaning and maintaining water reservoirs, and recreation statistics. The derived damage estimates will then be correlated with physical damage estimated by remote sensing devices. Differences in value of timber loss will probably vary within the San Bernardino Forest area, because of differences in predominant land use.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0457, ASSESSMENT OF VEGETATIVE DAMAGE

D.G. GILLETTE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Compile and analyze data on the effects of air pollutants on vegetation.

Approach: Review the state of the arts in deriving dose-response relationships between pollutants and combinations thereof, and plant injury. Provide technical assistance to the Agriculture Branch in determining those crops which are economically important and in need of further research.. Assist in the development of field studies and studies designed to measure the impact of air pollutants on suppressed growth or hidden injury. Develop, where feasible, economic damage functions for those crops where physical damage relationships are available.

Goal: Derive concepts for producting damage functions from research on air pollution injury to vegetation.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0458, STATE OF THE ART SURVEY (EFFECTS AND ECONOMICS) FOR METALS AND ALLOYS

F. HAYNIE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To assess the economic damage to metals and alloys caused by corrosion induced by air pollution.

Approach: Contract to survey corrosion and maintenance costs in four cities where information can be correlated with pollution levels. Extrapolate to national level. Cross check results by using amounts of materials exposed to pollution and known damage functions for specific metals or alloys.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0459, ENGINEERING COMPUTATION AND FORECASTING

M.W. HEMPHILL, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Initiate and continue and/or complete task orders in support of the Division's R&D program.

Description: This in-house service provides consultation in the fields of statistics, mathematics, computer technology and emissions forecasting. Principal applications of statistics include the design of experiments and analysis of data. Mathematical applications include the solution of differential equations and the development/evaluation of mathematical representations of process phenomena. Applications of computer technology provide support to mathematical and statistical computation as well as the storage and retrieval of data to facilitate forecasting.

The prediction of the quantity of pollutants, the degree of control and the cost of this control comes under forecasting. To form the basic forecasts and reconcile differences between reference data and other forecasts, it is necessary to construct and access inventories of emissions, sources of emissions, fuel consumption, control of emissions and related cost data.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0460, AIR POLLUTION AND PROPERTY VALUES
L. JOHNSON, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To improve the methodology of applying multiple regression techniques to assess the effects of air pollution on property values.

Approach: Refinement of present methods will be made and the results of existing studies will be applied and compared between different urban areas. Differences in property values will be related to different levels of air quality, housing characteristics and socio- economic variables.

Goals: To update existing property values studies with new census data. Previous studies which have been done using old census data will be compared with current studies.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0461, A SURVEY OF THE PROCEDURES FOR EVALUATING HEALTH COSTS DUE TO AIR POLLUTION
L. JOHNSON, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To review the techniques used to date and to outline alternative procedures.

Approach: A review of the literature, followed by a discussion with experts in the field and the Division of Health Effects personnel. From the discussions, possible alternative costing procedures will be developed.

Goal: To complete the literature survey and develop procedures for evaluating the cost of health effects attributed to air pollution.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0462, AN EMISSION AND CONTROL COST STUDY OF THE FEED AND GRAIN INDUSTRY
J.R. OCONNOR, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop comprehensive, reliable information for determining present and future costs for controlling air pollutant emissions of the feed and grain industry.

Approach: Emphasis will be placed on grinding, mixing, and handling operations generating dusts. Provision will be made to determine the future control costs for meeting specific (but as yet undetermined) emission standards. Cost and emission information will be obtained by use of a questionnaire generated by NAPCA. DAQED will obtain information with respect to the emissions (type and quantities) of this industry.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0463, AIR POLLUTION CONTROL COSTS ASSOCIATED WITH SOLID WASTE DISPOSAL
J.R. OCONNOR, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop information on the present and future costs of controlling air pollutant emissions associated with solid waste disposal.

Approach: With many communities banning open burning to alleviate air pollution, alternative methods of disposal must be considered. This study will develop cost information that may be used to evaluate these alternative methods of disposal. The principal pollutants to be considered will be the particulates, hydrocarbons and carbon monoxide. It is expected that the economics of disposal of junk autos will be an important aspect of this study. Information will be sought from other NAPCA groups as well as the Bureau of Solid Waste Management, the Bureau of Mines and the Department of Commerce.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0464, EMISSION AND CONTROL COST STUDY OF THE CEMENT INDUSTRY
J.R. OCONNOR, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop reliable control cost information for the cement industry.

Approach: The industry will provide information on their past expenditures for air pollution control. In addition, each company will provide an estimate of what their costs will be to upgrade installations to meet future emission standards. The principal pollutant to be considered will be particulate matter. An important aspect of this study will be an assessment of the value of recycled cement dust.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0465, TECHNICAL SUPPORT FOR THE THIRD & FOURTH COMPREHENSIVE COSTS REPORTS TO CONGRESS
J.R. OCONNOR, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To provide technical support in the preparation of the Cost of Clean Air Report.

Approach: Information on the costs of control for the sources understudy is supplied and review of the report at various stages of development is provided. Assistance is provided to the contractor in all phases of the report preparation. Extensive assistance with respect to the costs of control of mobile sources will be provided.

Goal: This task will be a continuing function for as long as the report is prepared under a contract.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0466, ENGINEERING AND ECONOMIC STUDY OF PRIMARY ALUMINUM SMELTING INDUSTRY
E.N. SMITH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop reliable, comprehensive information on the present and future cost of controlling air pollutant emissions for the primary aluminum smelting industry.

Approach: Current expenditures by the industry for air pollution control will be assessed on a national and regional basis. Provision will be made for estimating the future control costs required to meet specific (but as yet undetermined) emission standards. The principal pollutants to be considered in the study are hydrogen fluoride gas and fluoride particulates. An important aspect of this study is the assessment of the credit to be given for the use of collected fluoride material returned to a basic process. The information is being obtained by contract with a qualified organization.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0467, ANALYSES OF DATA & A REPORT ON RELATIONSHIPS BETWEEN SOCIO-ECONOMIC LEVELS OF AIR POLLUTION IN CHICAGO CENSUS TRACTS (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Air pollution has been related to health status by the results of a number of studies. It follows that poor health resulting from air pollution could lead to reduced learning abilities, subsequent lowered earning capacity and finally inability to move up from lowest socio- economic levels as a preliminary to subsequent investigations to determine if there is a cause-effect relationship.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0468, DEVELOPMENT OF A PACKAGE OF ECONOMICALLY IMPORTANT MATERIALS TO MONITOR THE DAMAGING EFFECTS OF AIR POLLUTION
J. UPHAM, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

1. AIR QUALITY

Objective: To develop a package of economically important materials to monitor the damaging effects of air pollution.

Approach: Economically important materials which are specifically susceptible to damage by SO sub 2, O sub 3, NO sub 2, or particulates will be selected for laboratory evaluation. A minimum number of controlled exposure chambers will be constructed so that both direct and interaction effects of pollutants can be studied to determine the most efficient techniques to use. Damage relationships expressed as cost as a function of pollutant concentration will be established.

Goals: Select materials, construct exposure chambers, design and evaluate experimental procedures.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0469, STATE OF THE ART SURVEY (EFFECTS AND ECONOMICS) FOR ELECTRONIC COMPONENTS

J. UPHAM, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To assess the economic damage to electronic components caused by air pollution.

Approach: Contract to survey manufacturers to establish rejection and failure rates that may be attributed to air pollution.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0470, DAMAGE FUNCTIONS

T. WADDELL, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop functional relationships between damages from air pollution and air pollution levels for an approach to defining the benefits of controlling pollution.

Approach: Assessment of damages in the areas of health, vegetation, property values, materials degradation, and soiling will be analyzed and utilized in a benefit/cost applicability for optimum pollution control.

Goal: To select damage areas in which functions can be developed, propose descriptive research in these areas, and examine rationale behind the use of these functions in benefit/cost analysis.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0471, GROSS DAMAGE ESTIMATES

T. WADDELL, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To systematically review and update economic estimates of air pollution damage. This task entails a continuous review of available data and periodic revision of damage estimates.

Approch: This task includes the critical review and documentation of gross damages from air pollution as related to particular receptors or pollutants. The results of such a project are to determine and substantiate reasonable estimates of damage based upon available data and to provide guidelines and recommendations for improving said estimates.

Goal: The output of this effort is to provide the 'best' estimate of gross damages from air pollution within the limitations of available data. Such estimates will provide valuable input into major policy decisions within this organization.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0472, FOSSIL FUEL COST AVAILABILITY MODELS

C. CHILTON, Battelle Memorial Institute, *Columbus, Ohio* 43201

Develop a model for simulating the availability of fuel on a short and long run basis. Calculate the distribution of fuels to the nation and determine their price in each area. Prepare a user's manual for the program. Simulate the impact of various policies and air quality control strategies on the distribution and price of fuels over the nation. Determine the sensitivity of the model of input parameters. Determine the sensitivity of the demand schedule for fuels to the control cost of sulfur oxides and the minimum acceptable selling price for each type of fossil fuel.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0473, ESTIMATE LEVEL AND COST OF AIR POLLUTION

UNKNOWN, Carnegie Mellon University, Graduate School, *Pittsburgh, Pennsylvania* 15213

1.0474, MINERAL FUELS AND THE ENVIRONMENT - THE CASE OF INDUSTRIAL FUEL USERS

R.L. GORDAN, Penn. State University, Graduate School, *University Park, Pennsylvania* 16802

Assuring adequate availability of energy without creating undesirable environmental effects is a matter of urgent concern in the United States. In recent years the importance of improved environmental quality has also become widely recognized. Fuel producers and users have generated much serious environmental damage and, therefore, much of the corrective action has been directed at these industries. As specialists on energy economics have long argued, the difficulties are complicated by the mass of older policies affecting energy supply. Research is needed on the ability to reconcile these new and existing policies with the demand for energy.

This study will examine the impact of different sets of government policies on the supply and demand for fuel for such industries as electric power generation and steel production. Both the new environmental, health and safety programs as well as more established programs such as import controls and natural gas regulation will be considered. The objective is a systems analysis of the complexities of these markets. Models of the critical sectors of the economy involved will be built and used to analyze the impacts of alternative policies.

SUPPORTED BY U.S. National Science Foundation

Air Quality Research Concerned With Standards, Management, Social Attitudes, Legislation, and Related Subject Areas.

1.0475, ALABAMA ENVIRONMENTAL STUDY-CONFERENCE PROJECT

R.K. RAINER, Auburn University, School of Engineering, *Auburn, Alabama* 36830

The Alabama Environmental Study-Conference Project is designed to promote interactions between university faculty and graduate students and state and local governmental officials in areas of environmental concern--air, water and land pollution.

A first step will be a survey of the status of pollution and control measures in Alabama, followed by a conference which will include representatives of business and industry, state agencies, cities and counties, and state legislators.

The report resulting from the survey and conference is intended to be used as a reference for planning the conservation of resources and for abatement of serious pollution problems.

SUPPORTED BY U.S. National Science Foundation

1.0476, COMEX AIR POLLUTION COMPUTER RESEARCH PROJECT

K.W. LEFFLAND, Univ. of Southern California, School of Public Admin., *Los Angeles, California* 90007

The Comex Research Project has as its purpose the development of improved teaching techniques for the University's Air Pollution Control Institute. The major research aims of the Project are: A. The development of a gaming simulation for air pollution control students and professionals (APEX); B. The development of Supplementary Training Exercise Programs; C. The expanded use of APEX throughout the country; D. The formation of an Air Pollution Simulation Laboratory.

APEX is now operational and has been incorporated into the program of the Air Pollution Control Institute. To enhance the APEX simulation game, Supplemental Training Exercise Programs (STEPS) have been developed. They provide an additional arena for gamed interactions in pollution control regulations, public hearings, court actions, budget proposals, and administrative functions. Comex is expanding the use of the APEX game throughout the country to benefit professional air pollution control groups and other interested agencies. To achieve this goal, we are developing a series of seminars to demonstrate APEX to professionals, emphasizing the value of air pollution control simulation models as an aid to management decision-making and understanding the complexities of the metropolitan environment. The objectives of the Air Pollution Simulation Laboratory are to: A. Provide an environment for advanced or special students to perform research functions and advanced projects; B. Furnish a vehicle through which APEX seminars may be conducted; C. and, serve as a collection, demonstration, and dissemination point for related research, particularly in the field of simulation.

1.0478, FOR SEMINARS AND STUDIES ON ENVIRONMENTAL ARTS AND SCIENCES, POPULATION GROWTH, URBANIZATION, POLLUTION, AND RELATED SUBJECTS
B.E. WILLARD, Thorne Ecological Foundation, *Boulder, Colorado*

The Seminar on Environmental Arts and Sciences is designed to: 1. Develop an appreciation for the principles and applications of the science of ecology as a foundation for environmental arts and sciences; 2. Examine the relationship of an environmental ethic to various basic scientific and cultural disciplines; 3. Offer an intensive exploration of ecological principles for leaders in business, industry, government, politics, education, religion, the professions, the arts, and the communications field; 4. Enhance the quality of citizen leadership on environmental concerns--oriented to the broad view of ecology and conservation.

The Seminar on Environmental Arts and Sciences examines the principles of ecology as they operate in a field setting under expert leadership from the nation's top ecologists. Other staff are drawn from diverse backgrounds--physical and social sciences, environmental design, law, government, politics, industry, communications, the arts, education--to apply these scientific principles in their human context, so as to build a concern for the physical and biological environment. The formal program is designed to stimulate thought and dialogue among participants and staff. The interactions initiated produce a continuing search into ecological, social and economic relationships of our environment. These processes continue during mealtimes, around the pool, and often long into the night. Participants, in scheduled and impromptu discussions, probe the many complex problems of maintaining a viable quality environment on this earth. These opportunities provide a total immersion in facets of world ecology and social and economic systems, as well as aesthetic and ethical considerations. They result in an intellectual and emotional experience that enable one to remold his thinking about the world in which he lives.

SUPPORTED BY William H. Donner Foundation Incorporated

1.0479, DYNAMIC PROCESSES
L. MACHTA, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302 (001137)

Technical Objective: Synthesis & coordination of turbulence, research, and modelling efforts.

Approach: Arrange for intra-laboratory research exchange through the medium of meetings, intra-laboratory exchange of staff, and frequent travel by laboratory scientists to pertinent locations. Augment interaction with other ESSA and non-ESSA research groups through seminars, visits, and discussions. Develop diffusion models on which computer time stepping criteria and core limitation for detailed diffusions and turbulence models can be tested. The Deputy Director will represent the Dept. of Commerce on the U.S. Japan Air Pollution Panel at the planned meeting in Tokyo late in April of 1971.

Progress: The staff attended an international symposium on atmospheric chemistry and radioactivity. Three intra-laboratory meetings were held to exchange scientific results and plans. Numerous technical society meetings were attended by various laboratory personnel and these included visits to universities and ESSA laboratories, where possible. Participated in many planning studies and requirement evaluation for global geophysical monitoring. A revised and improved carbon dioxide measurement system was arranged for the Mauna Loa Observatory. A symposium was held on the requirements for radiation monitoring, solar radiation measurements in connection with aerosol pollution and a new system designed for installation at Mauna Loa. The Director participated in a UK-US high level scientific meeting on emerging problems of environmental quality at the request of the Office of Science and Technology.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

1.0480, THE THEORY OF MAN-ENVIRONMENT RELATIONSHIPS
M.E. GARNSEY, Univ. of Colorado, Graduate School, *Boulder, Colorado* 80302 (000031)

To attempt a general statement of the theory of man and his environment.

Through twice monthly meetings of working seminars at which papers and reports on specific topics will be given. The findings are to be published.

A. During the proceeding year six presentations were made on weather modification and eight presentations on air pollution in the Denver areas. B. (Supplemental) Meetings have been held twice monthly rather than once a month. Discussion papers are recorded, transcribed, edited and circulated to the seminar members. Purchasing printed materials which the library does not acquire.

SUPPORTED BY U.S. Dept. of Commerce - E.S.S.A.

1.0481, PUBLIC POLICY INTERVENTION IN INTER-INDUSTRY FLOWS OF GOODS AND SERVICES TO REDUCE POLLUTION
J.S. GILMORE, Univ. of Denver, Graduate School, *Denver, Colorado* 80210

The objective is to develop methodology for analyzing the flow of pollution-creating products in one sector of the market system of the United States, and to identify points where public policy intervention might affect economic decisions on production processes to reduce pollution. The research will involve economists, public policy analysts, chemical engineering faculty, and law school faculty in the collection and analysis of information by which to identify high pollution inputs and processes, identify substitution possibilities and control capabilities, inventory public policy mechanisms which may encourage these pollution-reducing activities, and develop a methodology which may be widely applied.

Using the Office of Business Economics (OBE) input-output tables, and focusing on the petroleum refining and related products industry, the high-pollution inputs and outputs to each phase of the manufacturing-use-disposal cycle will be identified. Studies will be made of substitution possibilities and opportunities for pollution control, of existing and proposed public policy incentives and constraints affecting manufacturing, and of alternative control procedures. An attempt will be made to apply the methodology developed to parts of the entire U. S. product system depicted in the OBE tables.

1. AIR QUALITY

1.0482, AWARENESS OF AIR POLLUTION AND ITS CAUSES IN A NUMBER OF COLORADO COMMUNITIES
R. LOOMIS, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00095)

OBJECTIVE: During 1970-71 a second phase of work on public awareness of air pollution in Colorado will be initiated. Phase one of this project was concerned with a general attitude survey of several Colorado communities designed to measure public attitudes toward the problem of air pollution. In phase two, attitudes toward air pollution will be correlated with perceptions of air quality. Both field and laboratory methodology will be employed.

APPROACH: Repeated independent samples of households in north Denver known to be among the heaviest air pollution areas in Colorado will be surveyed on days varying in pollution level. Respondants will be asked their perceptions of the air quality on that day and attitudes about air pollution in general. The surveys will extend over a year. Concurrently with the field sample, a laboratory study will be performed to assess judgements of air quality from a series of photographs. The methodology of signal detection theory will be employed in the laboratory work.

PROGRESS: The investigation has been designed to survey public attitudes towards air pollution in a number of Colorado communities. Work has been completed on the review of background literature and initial development of the survey instrument. In addition, contact was made with a number of resource persons in the pollution area and their suggestions incorporated into the study. These suggestions included adding items, measuring knowledge of actual costs for pollution abatement, opinions toward groups and agencies responsible for pollution control and knowledge of consumer products (other than automobiles) that create pollution. Details of the sampling procedure are currently being worked out and the completion of survey data collection is scheduled for the end of March.

SUPPORTED BY Colorado State Government

1.0483, THE ORGANIZATIONAL FACTORS IN AIR POLLUTION CONTROL
M.E. ECKSTEIN, Southern Connecticut St. Col., Graduate School, *New Haven, Connecticut* 06515

In September of 1966, the project staff - then located at Center for New York City Affairs, New School for Social Research -- began a three-year project of research on the role of organizations involved in the control and abatement of air pollution in the New York metropolitan region. This research has focused on relationships of government agencies and business firms in air pollution control.

The major areas of data collection and analysis have been: (1) legislative and legal context of air pollution abatement programs in the New York metropolitan region; (2) principal structure and organization of control agencies at various levels of government; (3) procedures used for control, including policy and guidance; (4) patterns of coordination and interaction among control agencies, including special studies of procedures used in air pollution emergency situations; and (5) structure, procedures and policies of organizations which are generally designated as major sources or air pollution.

The collection and collation of these data have been largely completed, with the quantifiable data coded and on punched cards. The fourth year of the project will be devoted to the final phases of analysis of the data.

1.0484, EVALUATION OF FACTORS RELATING TO THE PROPOSED DESIGNATION OF AIR QUALITY CONTROL REGIONS
UNKNOWN, Linton Mields & Coston Inc., *Washington, District of Columbia*

The contractor will study urban areas under consideration as Air Quality Control Regions and make reports for use in the development of Consultation Reports by the Office of Regional Activities. Thirteen regions will be selected from the areas proposed by NAPCA on March 24, 1969. The study will consist principally of an examination, evaluation, and report related to the governmental jurisdictions having planning and operating authority within the regional area and their relationships to air pollution control. NAPCA will provide engineering data such as diffusion models and emission densities to the contractor for use in such evaluations. The contractor will prepare projections of the planning needs for the region, taking into account population and economic growth trends, as well as other contributive factors. Additionally, the contractor will prepare recommended courses of action and alternative solutions for strengthening air pollution planning in each region studied.

1.0485, PARTIAL SUPPORT OF THE COMMITTEE ON GEOLOGICAL SCIENCES
J.W. BERG, Natl. Academy of Sciences, *Washington, District of Columbia* 20037

The Committee on Geological Sciences of the National Academy of Sciences-National Research Council is undertaking a two-year study of the present and potential role of the geological sciences on human affairs. A sharply focused report for the public, Congress, earth scientists, and others on new developments in and applications of the geological (and geophysical) sciences is expected to result. Major topics of consideration include the relationship of the geological sciences to: 1) natural resources, 2) waste management and pollution control, 3) land utilization, 4) human health, 5) defense, and 6) cultural impact and need for knowledge of the earth.

SUPPORTED BY U.S. National Science Foundation

1.0486, COMMITTEE ON ATMOSPHERIC SCIENCES
J.R. SIEVERS, Natl. Academy of Sciences, *Washington, District of Columbia* 20037

The National Academy of Sciences proposes the continuation of the activities of the Committee on Atmospheric Sciences for the calendar year 1971. At present, these activities are supported jointly by NOAA and the NSF under contract C-319, Task Order No. 9.

The Committee on Atmospheric Sciences seeks to encourage the establishment of a balanced national scientific effort in atmospheric sciences and to stimulate U. S. participation in pertinent international programs. Following up on the recent summer study at Friday Harbor, the CAS will continue to examine the pollution of the atmosphere and the need for information on this. Problems of short range prediction and predictability of events such as local severe storms will be studied this coming year also, including the possible extension of numerical forecasts into mesoscale events. The appropriate technology for sensors both 'insitu' and remote, will be studied.

SUPPORTED BY U.S. National Science Foundation

1.0487, FEDERAL CONSTRUCTION COUNCIL
UNKNOWN, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

Progress: Task Groups of the Federal Construction Council met seven times during the period, with accomplishments as follows: prepared technical program for 68-69 operating year; met with administrators of supporting Federal agencies; studied administrative and technical problems of mutual interest to all agencies. FCC monitored work on 18 formal studies under way, as follows: air and water infiltration through non-load bearing exterior walls; air pollution (phase I); thermoplastic piping for potable water distribution systems; Federal fire standards; feasibility of standardizing design criteria; prevention of water pollution from construction activities; effectiveness and efficiency of air conditioning systems; revision of FCC Technical Report No. 44 (Boiler Rating Criteria); value engineering; seasonality in construction;

testing and balancing air conditioning systems after installation; technology forecasta-construction materials, techniques, and equipment; techniques for comparing actual performance of buildings with design objectives; humidification in buildings; plastic insulation of mechanical systems; revision of FCC Technical Reports No. 30R-64 and 39-64 (or underground heat distribution systems); Directory of Computer Programs; and air pollution (phase II). Also during the current year FCC has undertaken, as informal investigations, studies of three matters of far-reaching importance: modularization in construction; computerized specifications; and project management control. One informal investigation--on unfired water heaters--began in the previous year--has been completed.

1.0488, AIR POLLUTION MODELING - INTEGRATION OF TECHNICAL AND SOCIO-ECONOMIC CONSIDERATION

L.R. BABCOCK, Univ. of Illinois, School of Engineering, *Chicago, Illinois* 60680

Successful air quality management must integrate various scientific and technical facets with socio-economic implications. Computer simulations are a practical method for combining diverse facets toward first understanding the environmental system and thence for evaluating alternative pollution control strategies.

Individual meteorological, geographic, and economic air pollution models have been created. Energy parameters provide a common denominator for combination of these individual efforts.

The proposed research would stress verification and application of a generalized urban simulation model developed by the investigator. Example applications include evaluation of alternative settlement patterns, evaluation of alternative pollution control strategies, or incorporation of the model or some of its parts into simulations constructed by others.

1.0489, DESIGN DETAILED PERFORMANCE SPECIFICATIONS FOR THE DIFFERENT TYPES OF AIR QUALITY SURVEILLANCE NETWORKS

R. GREELEY, Mitre Corporation, *Bedford, Massachusetts* 01730

Objective: To provide State and local agencies with detailed specifications for bid proposals related to the acquisition of an air quality surveillance network.

Approach: A contract will be awarded to develop the specifications for the bid packages put together by State and local agencies. Performance characteristics, sensitivity and reliability will be spelled out to enable the local agencies to have a better bid package before calling for bids for the acquisition of their air quality surveillance system. It is envisioned that five sets of specifications will be prepared for sampling networks ranging from simple mechanized devices to real time telemetry.

Goal: To prepare and disseminate a set of performance specifications for the different types of air quality surveillance systems.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0490, COLLECT AND STORE CURRENT NON-NAPCA AIR QUALITY DATA

R. GREENLEY, Mitre Corporation, *Bedford, Massachusetts* 01730

Objective: To incorporate the aerometric data collected by agencies outside NAPCA into a central data base, the National Aerometric Data Bank.

Approach: The existing contract with MITRE Corp. will be continued. Additional agencies will be contacted to acquaint them with the scope and purpose of this collection effort. Procedures will be worked out for the future transmission of this data to NAPCA in a routine manner. The data received will be converted to the SAROAD format and stored in the National Aerometric Data Bank. Summaries and reports on selected pollutants will be prepared for input into NAPCA reports on national air quality. Hopefully this effort can be phased over from MITRE to NAPCA in FY 72.

1.0491, THE EFFECTS OF AIR POLLUTION ON INTERPERSONAL BEHAVIOR

L.G. RIVLIN, City University of New York, Graduate School, *New York, New York* 10031

The proposed study is concerned with the relationship between observable interpersonal behavior and levels of air pollution. Using procedures developed in studies of other environmental settings, we would like to gather concrete data on how interpersonal behavior is influenced by the level of pollutants in the air. As yet, this area of research has not previously been explored. One of the immediate objectives of the present exploratory proposal is to uncover meaningful hypotheses that would focus on the specific aspects of behavior relevant to reactions to air pollution.

There are two long-range goals that could emerge from this approach. The first would be the attempt to relate the behavioral data obtained to the existing information on the physiological effects of air pollution. The second is concerned with our continuing interest in collecting a large body of data in a variety of settings on the role of physical surroundings on behavior. It is hoped to relate the effects of air pollution on interpersonal behavior to the whole range of problems dealing with the impact of the urban setting on human behavior.

1.0492, STUDIES FOR A SURVEY OF ENVIRONMENTAL POLLUTION, CONDUCTED BY THE NEW YORK CITY SCIENCE AND TECHNOLOGY ADVISORY COUNCIL

UNKNOWN, Columbia University, Graduate School, *New York, New York* 10027

The New York City Science and Technology Advisory Council, created three years ago, serves in an advisory capacity to the Mayor, bringing specialized knowledge to bear on the analysis and solution of urban problems. In defining areas for basic and applied research, it has had the collaboration of the School of Engineering and Applied Science of Columbia University, which provides technical advice and helps obtain factual data. The Council is currently working on recommendations for dealing with air and water poilution.

1.0496, COLLOQUIUM OF INTERNATIONAL AIR POLLUTION SCIENTISTS
A. STERN, Univ. of North Carolina, N.C. Air Pollution Symposium, *Chapel Hill, North Carolina* 27514

The Second International Air Pollution Conference of the International Union of Air Pollution Prevention Associations at the Sheraton Park Hotel, Washington, D.C., December, 1970, is expected to attract the principal Air Pollution scientists of the world to the United States. While attending the conference, these scientists will be fully occupied in presenting, discussing or listening to technical papers, keynote addresses and session summarizers; attending formal social events and viewing the conference exhibit area. No structured means will be provided to allow these scientists to get together for less formal discussions and information exchange, although some of this will undoubtedly take place in unstructured fashion.

What is herein proposed is to provide an opportunity for a selected group of these scientists to meet during the week following the conference for such less formal discussion and information exchange. It is believed that this will broadly clarify air pollution research and training objectives in both the United States and foreign countries and thereby stimulate new activities in these areas.

1.0497, LAW-RELATED RESEARCH ON SCIENTIFIC UNCERTAINTY AND TECHNOLOGY ASSESSMENT
C.G. HAVIGHURST, Duke University, School of Law, *Durham, North Carolina* 27706

Some of the most vexing issues now facing American society revolve around scientific judgments about the nature and extent of particular alleged hazards to life and health. For example, the health effects of air pollution and radiation are at issue in ongoing public debates, yet the necessary determinations depend upon scientific judgments that are highly uncertain. These debates problems that will increasingly be encountered in confrontations between science and law in the emerging field of technology assessment

To gain a better understanding of the nature of these problems and of the means for dealing with them, the Committee on Legal Issues in Health Care in conjunction with a number of the nation's law reviews will undertake a series of student research and writing projects on ten specific issues of current public interest. Each project will in effect be a case study on a topic which is characterized by a lack of definitive scientific understanding of the subject matter, necessitating legal decision-making in a climate of uncertainty. Included will be studies of cases concerning the health effects of air pollution , radiation, pesticides, cyclamates, and oral contraceptives. Some studies may also examine potential issues arising from advances in bio- medical engineering.

1.0498, BASE STUDY OF THE STATUS OF ECOLOGICAL RESEARCH
H. BOND, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Establish a basis for planning and implementing a broad based ecology research program on the effects of environmental pollutants on selected ecosystems.

Approach: An ecologist assisted by technical manpower will 1) report on the general state of ecological research especially as applicable to air pollution effects and provide a list of references; 2) determine the current areas of research and the facilities involved and/or available and 3) contact investigators throughout the world and establish working communications with them.

Goals: Subsequent to completion of the report, long and short term planning for research on the effects of air pollution on selected ecosystems wil be initiated. Alternative courses of action may be provided through a systems analysis contract jointly handled by the ecologist and the Office of the Director, BCS.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0499, NATO/CCMS
K.L. CALDER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

To assist NATO member countries in their efforts to solve air pollution problems. Particular attention will be given to the development of urban diffusion models for Ankara, Turkey and possibly for other member country's cities.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0500, PRIVATELY OWNED POWER PLANTS - FEDERAL CONTRACTS
J. COPELAND, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Compile information on Navajo, Kapairwitz, Mohave, and Four Corners power plants by July 15, 1970. Meet with USDI ad present NAPCA air pollution control recommendations by August 1, 1970. Review all proposed contracts and air pollution control plans and make comment upon them within 60 days after receipt.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0501, CAVEN POINT INCINERATOR EVALUATION
J. DEALY, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Participate in test of Caven Point Incinerator, U.S. Army, to determine compliance with Federal emission standards. Provide source test team as part of a larger project to measure visible and other particulate emissions during oper[illegible] Testwork to be complete by November 1,1970. Provide te[illegible] capabilities for preparing report on results of test. Report to be completed by February 1, 1971.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0502, STUDY OF THE SOCIAL AND ECONOMIC IMPACT OF ODORS - PHASE II
R.C. DICKERSON, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop an efficient and inexpensive method that would provide an adequate assessment of the social and economic impact of odors on a community.

Approach: A public attitude survey will be conducted in test and control areas along with odor measurements to obtain data needed to develop an odor evaluation procedure.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0503, ADEQUACIES OF ELEMENTS OTHER THAN CONTROL REGULATIONS IN PLANS FOR SO2, PAKTICULATES, CO, HYDROCARBONS & OXIDANTS (ABBREV)
J. FARMER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The elements of the plan other than the control regulations include (1) legal authority, (2) surveillance, (3) emergency episode plan, (4) timetable for compliance and (5) resources. This evaluation will be coordinated with various other divisions in NAPCA. A report of the total evaluation with recommendations will be prepared and forwarded to the Commissioner, NAPCA for his review.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0504, THE STATES NECESSARY CHANGES AND MODIFICATIONS IN THE IMPLEMENTATION PLANS FOR

SO2 - PARTICULATES - CO - HC AND OXIDANTS (ABBREV)
J. FARMER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Once the implementation plans are received, a preliminary review will be conducted to see if all the required elements are present. If any are missing, the states will be advised informally. If they don't respond to the informal approach, a formal course of action, including formal notification from the Commissioner, NAPCA, will take place. The same steps (informal and formal notification to the states) will be undertaken for the final evaluation of the plans.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0505, DETERMINE IF THE CONTROL REGULATIONS WILL ACHIEVE THE AIR QUALITY STANDARDS FOR SO2 - PARTICULATES - CO - HC AND OXIDANTS (ABBREV)
J. FARMER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

This will be accomplished by a simulation model. Assistance in modeling will be obtained from the Meteorology Branch, Division of Abatement. The inputs required for simulation modeling are emission inventory, meteorology, air quality and growth data. These will be available, in most cases, from the states in cooperation with the technical assistance effort from DCAD. When the input data are not available from the states, appropriate in-house efforts will be undertaken.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0506, INFORMATION AND RESEARCH EXCHANGE BETWEEN SCIENTISTS
W.W. HECK, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Develop and keep updated a Directory of scientists involved in agricultural aspects of air pollution and publish a quarterly research oriented newsletter.

Approach: A list of United States and foreign research scientists has been developed and distributed to interested personnel. This list will be revised and brought up-to date as of June of each year. The preparation and distribution of a research newsletter will be implemented in cooperation with APTIC for a distribution to the research scientists on a quarterly basis. Such a publication would permit more rapidly circulation of new and important findings in the area of research in air pollution and agriculture.

Goals: Develop and information and research exchange between scientists ivolved in agricultural aspects of air pollution.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0507, LABORATORY SUPPORT IN THE ENFORCEMENT OF IMPLEMENTATION PLANS
S. HOCHHEISER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

In cases where air quality levels aren't being achieved and reasonable enforcement is not being taken, laboratory support will be provided to determine the degree of compliance with source restrictions. This support will consist of fuel sulfur analyses, analyses of raw materials and products and of samples collected by source testing personnel. Resultant measurements will be used to quantitate excessive emissions in light of air quality goals to provide assistance in court actions initiated by the Attorney General.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0508, REGIONAL CLIMATOLOGY
G. HOLZWORTH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Provide for quick tabulation and summation of meteorological or climatological data for a specific area during episode. Data may be required for documentation as a matter of public record. Services probably to be provided by the National Weather Records Center, ESSA or by the Weather Bureau, is not readily available by DM.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0509, COMMUNICATIONS
G. HOLZWORTH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Monitor air pollution potential forecasts, disseminated by the Weather Bureau's National Meteorological Center, to ensure proper issuance of advisories or meteorological information to NAPCA officials during episodes of adverse weather conditions.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0510, CLIMATOLOGY
G. HOLZWORTH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Provide available diffusion climate data and its analyses in a format useful for assessing air quality management of power plants, particularly with respect to plant siting criteria in consideration of long range planning.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0511, AIR POLLUTION POTENTIAL CLIMATOLOGY
G. HOLZWORTH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Publish air pollution potential climatological data, from analyses of wind speed, mixing depth, and other meteorological data based on 62 Weather Bureau radiosonde stations.

Prepare air pollution potential climatology and other data for long range planning purposes and air quality management, reviewing quality statistics to air pollution potential.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0512, SOCIAL IMPACT OF AIR POLLUTION ON THE PHILADELPHIA AIR QUALITY CONTROL REGION
L. JOHNSON, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To formulate and test hypotheses on the sociological aspects of air pollution in the Philadelphia area.

Approach: Personnel in NAPCA, along with experts in the Social Science field, will be contacted in order to define hypotheses of interest. The data base available from the recent study in the PENJERDEL region will be utilized in examining the hypothese.

Goal: To complete the study, and employ the results to establish a basis for further research in the area of the social impact of air pollution.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0513, HEDONIC EVALUATION OF ODORS
A.C. JONES, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To determine public attitudes toward odors of different quality.

Approach: Select three areas within a city, one area exposed to an 'unpleasant' odor source, another area exposed to a 'pleasant' odor source and the third area exposed to no odor. The public attitudes in the three areas would then be surveyed and compared for significant differences. The city would be selected from among those employing the scentometer for enforcement purposes. The odorous areas should have a history of being exposed to at least a reading of scentometer No.2 odor strength; persons experienced in the use of the scentometer have stated that 'a No.2 odor, irrespective of its quality, will cause complaints; 03 and 04 odors are considered serious nuisances, particularly when they are frequent or persistent.' The history of the areas should be determined fron the local control agencies, if possible. If not, then it will be necessary for the contractor to do his own sampling.

1. AIR QUALITY

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0514, SURVEY FUEL ADDITIVE INFORMATION NEEDS AND IMPROVE RETRIEVAL OF DATA
J. MERSCH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Commence development of a computer program to extract information from fuel additive registration notification forms and to present it in usable form to potential users throughout NAPCA.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0515, REGISTER FUEL ADDITIVES
H. MILLER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Register fuel additives per section 210 of Clean Air Act and make this information available for NAPCA study and analysis.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0516, DATA PROCESSING - FEDERAL INSTALLATIONS
F.B. ORR, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The GAS inventory of real property, Form 5049, and Formats A and C (or their revisions) individually contain basic data on Federal facilities. These data are being processed into computer form, and are currently being used in preparing emisson inventories for Federal facilities in AQCR's. Additional studies planned or in process include fuel use trends, compliance with appropriate regulations, refuse disposal practices, and summaries by state or local jurisdictional areas. Once the basic data is processed, the data bank will be expanded to include process emissions, aircraft and maritime operations emissions, and other specialized activities.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0517, DEVELOP NEW PROCEDURES FOR THE EOCC
D. TYLER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The purpose of this task is to expand the operation of the EOCC and develop procedures for conducting expanded operations as well as improving the present operations. The task will include the following: 1. Expand the AQ data network from the present 6 sites to 26 sites. The expanded network will use state AQ monitoring sites. 2. Increase the communications capabilities to handle the increased AQ data, the issuance of HAPPA bulletins and action advisories to the states. Various communications systems such as teletypes will be considered and recommendations made for their use in the EOCC. 3. Assemble or work with DAQED elements in the development of emissions inventories. 4. Work with the Argonne National Laboratory in designing a procedure for developing incident control models for episode prone areas.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0518, OPERATION OF EOCC
D. TYLER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The purpose of this task is to conduct the day to day operation of the EOCC using the procedures specified in the SOP. This task will include the following functions: 1. Acquire and analyze air quality and meteorological data. The data will be received daily and analyzed against the episode criteria. 2. Disseminate the HAPPA bulletins as required. This task is presently being done by the Meteorology Branch. 3. Make recommendations as to what Federal action is called for in any episode area. 4. Maintain a log book on the daily activities of the EOCC. 5. Prepare and disseminate after action reports on the EOCC's actions during a particular episode.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0519, EVALUATE EPISODE SECTION OF AQCR IMPLEMENTATION PLANS
D. TYLER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The EOCC will assist other DA elements in evaluating the episode section of each AQCR Implementation Plan. Such evaluation will insure that the episode plans developed for each AQCR are capable of preventing emergency episode situations. Each plan will be examined to assure that the legal authority for controlling episodes exists and that the plan shows that the state agency has the capability of operating an episode contract program.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0520, EVALUATE SURVEILLANCE DATA
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Examine surveillance fleet data for compliance with Federal emissions standards.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0521, DEVELOP STANDARDS FOR FEDERAL FACILITIES
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Based on health-related values, develop air quality standards applicable to Federal facilities for various air pollutants.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0522, STATE ASSISTANCE IN STANDARDS FORMULATION
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Provide assistance to the several States in the formulation of Regional standards for 5 pollutants covering some 57 Regions by comparing proposed standards with reference air quality standards, with emphasis on appropriate averaging times. Making presentations at public hearings to provide guidance to the participating public. Pollutants of current concern are: SOx, suspended particulate matter, oxidants, carbon monoxide, and hydrocarbons.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0523, EVALUATION OF ADOPTED AIR QUALITY STANDARDS
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Review adopted state standards for 5 pollutants (SOx, particulates, oxidant hydrocarbons, CO) for 100 air quality control regions, in terms of: proper protection of the health and welfare of the populace, existing air quality, compatibility in Interstate Regions and, public participation in standard setting. Prepare complete concise summaries of reviews together with recommendations on approval.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0524, DEVELOP REFERENCE AIR QUALITY VALUES
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Based on criteria for HC, CO, NOx, lead, fluorides and polycyclic organic matter, develop values of air quality as a function of averaging times for association with biological and nonbiological effects.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0525, DEVELOPMENT OF REFERENCE AIR QUALITY STANDARDS

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Determine concentration-time relationships for pollutants applicable to effects on health, vegetation and materials from appropriate Criteria Documents. Determine appropriate averaging times for various effects. Develop reference standards in terms of effects and outline complete review techniques. Coordinate reference standards and review techniques with higher echelons within NAPCA. Prepare in final form standard procedures for review of adopted State standards for the following pollutants: (1) carbon monoxide, (2) photochemical oxidants, (3) hydrocarbons, (4) lead, (5) fluorides, (6) polynuclear organics, and (7) oxides of nitrogen.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0526, REVIEW AND PREPARATION OF CRITERIA DOCUMENTS FOR NO, F, ODORS (INCLUDING H2S) HCL, CL2 (GAS)

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To support the Office of Criteria and Standards in the public action of criteria documents.

Approach: As assigned prepare, review, or both, sections of criteria documents related to materials damage.

Goals: Prepare and/or review materials damage section for NOX and F.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0527, LEGISLATION AND REGULATIONS - AQCR PLANS

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Assist States in the development of adequate legal authority and emission control regulations for their respective AQCR implementation plans. Existing legislation will be evaluated for adequate authority to adopt emission control regulations, require registration of emission information, require permits prior to construction and operation; inspect and test facilities, enforce regulations through adequate sanctions and administrative orders and hearings, and implement emergency episode action. Emission control regulations will be evaluated to determine gaps in coverage and to judge consistency with modern control techniques, good practice and enforceability.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0528, LEGAL INFORMATAON HANDLING SYSTEM

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Develop and implement a legal information retrieval system. The system will be based on an accessable card file containing information on air pollution rules, regulations and legislation which have been adopted by the various States and local jurisdictions.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0529, EVALUATE THE EFFECTS OF SOURCE CONTROL PROGRAMS ON AIR QUALITY LEVELS

R.T. WALSH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

When air quality standards aren't being achieved and reasonable enforcement is not being provided, the degree of compliance with source restrictions will be evaluated to provide assistance in court suits. Visual surveys will be conducted and technical data will be assembled such that the effect of the excessive emissions can be evaluated. This information will be provided to the Attorney General for use in court actions initiated pursuant to the act.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0530, EFFECT OF CHANGES IN AIR QUALITY ON COMMUNITY ATTITUDES, INFORMATION SEEKING, AND KNOWLEDGE

R.G. MASON, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00890)

OBJECTIVE: To determine the level of public knowledge and information about and attitudes toward air conservation and to measure the effect of a deterioration in air quality on these interdependent attributes.

APPROACH: A theoretical model has been formulated that can be described mathematically as a system of simultaneous equations. Personal interview surveys of the general public in two Oregon cities will be conducted that will include measures of endogenous and exogenous variables. Each city will represent a known difference in range in air quality; one city experiences only nominal loss of visibility throughout the year while the second is subjected to continuous and severe deterioration in air quality part of the year. One survey will be conducted when visibility in both cities is high; the second survey when visibility is high in one city but low in another. Change scores of endogenous variables will be used to test the model. Analysis by two- stage least squares is planned.

PROGRESS: Initial phase of the study was to develop measures of the knowledge and attitude measures described in the theoretical model of the work plan. The first step was to locate published material concerning air pollution. Microfilm tapes of the daily newspapers in the two planned target areas and the Readers' Guide were surveyed and all material concerning air pollution was noted. Time interval, in all cases was the past 5 years--Jan. 1, 1964 through Dec. 31, 1968. Appropriate material from these sources was reproduced by Xeroxing. Coders trained to perform a content analysis of the Xeroxed material completed their coding and all statements--approximately 3,000--were typed on cards. A classification system was developed for separating statments into first, knowledge or attitude categories, and further, into mutually exclusive sub-categories. Intensive interviews of the general public in the target cities were completed, tapes transcribed, and a content analysis completed. As well, similar interviews were completed with professionals in the air quality field in Oregon and these interviews were transcribed and a content analysis completed.

1.0532, SECOND INTERNATIONAL CLEAN AIR CONGRESS, INTERNATIONAL UNION OF AIR POLLUTION PREVENTION ASSOCIATIONS, WASHINGTON, D.C. (ABBREV)

A. ARCH, Air Pollution Control Assn., *Pittsburgh, Pennsylvania* 15213

The International Union of Air Pollution Prevention Associations was founded in Washington in June 1964 at a meeting of representatives of six national air pollution prevention associations and held its first congress in London in 1966. The purpose of the International Union is to promote collaboration and exchange of information on air pollution problems and to organize, through its member associations, international congresses, the proceedings of which are published. For the Second Congress there have been organized program committees representing 35 countries plus the World Health Organization and the Pan American Health Organization. The program includes plenary sessions for keynote and summary addresses and technical sessions in six air pollution subject areas: chemistry and physics, meteorology, medicine, and biology, engineering, control administration, and community and area studies. This award defrays costs of simul

taneous translation services in five languages at plenary sessions aad in two languages at technical sessions.

F. CONTROL METHODS

Equipment, Abatement, and Operations Relating to Air Quality Control.

1.0534, AEROSOL FILTRATION IN SLIP AND TRANSITION FLOW
S.L. GOREN, Univ. of California, School of Chemistry, *Berkeley, California* 94720

The proposed research is an experimental and theoretical study of the pressure drop and aerosol filtration efficiency in fibrous media in the slip, transition, and free-molecular flow regines, i.e. when the mean free path in the gas is comparable to or larger than the diameter of the fibers. Motivation for this research stems from the expectation that filtration efficiency is significantly increased and pressure drop decreased under these conditions. Our experiments are to cover a wide range of Knudsen numbers, from 10 to minus 2nd power to 10 to the 2nd power, using carefully prepared monodisperse aerosols and carefully prepared fiber mats made from uniform diameter fibers. The results should be of use in designing reliable filters for removing particulate matter, including small biological particles, from gases.

1.0535, AIR POLLUTION CONTROL BY CATALYSIS
K. NOBE, Univ. of California, School of Engineering, *Los Angeles, California* 90024

The purpose of this research program is to investigate the elimination of pollutants formed in combustion processes (e.g., nitrogen oxides, sulfur oxides, carbon monoxide, hydrocarbons and oxygenated hydrocarbons) by heterogeneous catalysis. Catalytic studies on rate of oxidation and reduction, and on catalyst activity - time characteristics under the oxidizing and reducing exhaust gas conditions in the absence of and the presence of various catalyst poisoning agents are in progress.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0536, SULFATION KINETICS IN SO2 ABSORPTION FROM FLUE GAS
R.W. BARTLETT, Stanford University, School of Earth Sciences, *Palo Alto, California* 94305

A continued study of the kinetics of sulfur dioxide reaction with selected oxides is proposed. This work is related to the removal of sulfur dioxide from coal burning power plant flue gases. Continuous monitoring of weight change during sulfation of a suspended sample and infrared analysis of SO2 gases passing through fixed bed reactors are the principal experimental methods being used. The role of oxygen, water vapor and temperature are being determined. The role of pore diffusion is being followed by microprobe analysis and from rate variations with pellet size. Alkalized alumina and Bayer alumina plant solid wastes are the sorbents receiving primary attention. Both have significant sulfur loading capacities at flue gas temperatures.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0537, A STUDY OF SURVEILLANCE INSPECTION AND MAINTENANCE PROCEDURES FOR MINIMIZING AUTOMOBILE EXHAUST EMISSIONS (CAPE-13)
N. RICHARDSON, T R W Incorporated, *Redondo Beach, California* 90278

A contract presently in effect will acquire and develop the data necessary to determine to what degree various inspection, maintenance and surveillance systems are effective in reducing automobile exhaust emissions. It will develop exhaust emission inspection procedures which can be performed in a short period of time for both state-owned and state-franchised inspection stations. It will evaluate inspection instrumentation and develop a short driving cycle. In addition, vehicle parameters such as engine idle speed, spark timing, PCV system operation, and ignition system conditions will be studies and related to vehicle emissions. Deterioration of these parameters with mileage accumulation will also be studies.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0538, BASIC STUDY OF AIR POLLUTION WET-SCRUBBERS
S. CALVERT, Univ. of California, Air Pollution Research Center, *Riverside, California* 92507

The specific matter of the program will be the investigation of several gas treating mechanisms which show evidence of being especially effective. These subjects are as follows: 1. Gas contract with atomizing liquid. 2. Hot gas interaction with cold surfaces for (a) the removal of particles under the influence of combined inertial, thermal, and possibly mass flux forces and (b) condensation on particles due to radiative and convective heat transfer. 3. Gas contact with packed beds, including regular arrays of cylinders, etc., for the removal of particulates. (4) Gas contact with suspensions of adsorbent or reactive particles. (5) Develop a method for determining economic optimum scrubber designs for principal types and use it to evaluate new design approaches.

The aims of this work are to define the basic mechanisms involved in gas absorption and particulate collection in the above systems. The attainment of these specific aims will bring us nearer to the ultimate goal of being able to completely define the performance of gas scrubbing equipment. This will require an understanding of the basic mechanisms involved and of the effects of the all significant variables such as fluid properties, flow rates, system geometry, particle properties, etc.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0539, LOW EMISSION FUELS FOR VEHICLES
PEFFLEY, Univ. of Santa Clara, Graduate School, *Santa Clara, California* 95053

This project will represent the third phase of a study investigation the potential of methyl alcohol as vehicle fuel. It will concentrate on engineering development of an integrated system utilizing exhaust system waste heat to catalytically decomposed methanol to hydrogen and carbon monoxide.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0540, REDUCTION OF NITRIC OXIDE BY GRAPHITE
H.W. EDWARDS, Colorado State University, School of Engineering, *Fort Collins, Colorado* 80521

The major objective of the research program is to determine the conditions under which the rate and extent of reduction of nitric oxide by graphite are significant in terms of possible NOX emission control. While formation of reaction products is highly favored thermodynamically, there is considerable disagreement in the literature concerning the rate and extent of reaction between nitric oxide and carbonaceous materials at temperatures and compositions typical of those in automobile exhaust systems. Present plans also call for exploration of methods by which the graphite surface can be altered to favorably affect the reaction rate.

1.0541, TECHNOLOGICAL AND ECONOMIC FEASIBILITY STUDY OF ADVANCED POWER CYCLES AND METHODS OF PRODUCING NON-POLLUTING FUELS
F.L. ROBSON, United Aircraft Corporation, *Hartford, Connecticut*

Description: This is an analytical program for the purpose of defining fuel desulfurization and conversion processes and advanced- cycle control power stations which in combination will reduce or eliminate emissions of sulfur dioxide and other pollutants resulting from the combustion of high-sulfur coal and residual fuel oil. The program consists of estimates of the technical and economic feasibility of (1) clean-up processes for removing sulfur from fuel prior to combustion, (2) advanced-cycle power stations, and (3) integrated fuel clean-up processes and power stations. Processes and stations considered are those utilizing currently available technology, and those using technology judged to be potentially applicable in commercial configurations within both the next ten years, and the next twenty years.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0542, NAPCA/AISI SINTER PLANT EMISSION CONTROL DEVELOPMENT PROGRAM
UNKNOWN, Amer. Iron & Steel Institute, *Washington, District of Columbia*

Objective: Develop project plan and fabricate hardware.

Description: The purpose of this project is to develop and/or demonstrate, by joint cooperation between NAPCA and the AISI, new technologyy for controlling all emissions (particulates, sulfur oxides, fluorides and hydrocarbons) from the sintering process. Several approaches have been evaluated that make use of both bag houses with dry additive injection, aqueous scrubbers of various types and wet electrostatic precipitators. Until these processes are developed and demonstrated, a clear cut decision relative to their applicability to the industry cannot be made. This research and development program on control technology will provide the information to help make that decision and will hasten the application of controls of this emission source.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0543, ENGINEERING REVIEW CONSULTATION
R. CROZIER, Natl. Academy of Sciences, *Washington, District of Columbia* 20037

Objective: Initiate and continue and/or complete task orders in support of the Division's R&D program.

Description: The National Academy of Engineering will review engineering research, development, and demonstration programs of both government and industry in new and improved control technology for abatement of air pollution; analyze technical progress in air pollution control; identify technical or economic deficiencies or limitations to orderly scale-up; recommend new technical work or modification of existing work in order to achieve the most rapid development or process under consideration; recommend additional engineering and economic considerations and priorities; review HEW's program for balance and objectivity; perform such other additional work in the field of air pollution abatement and control including associated problems of potential water and land pollution; and report findings and recommendations as appropriate.

1.0544, AIR CLEANING
C.M. HUNT, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

Samples of dust have been collected from various room locations at NBS and at the Post Office Building in Omaha, Nebraska by means of high volume samplers. It is now possible to collect weighable amounts of atmospheric dust and compare airborne dust levels in building spaces with National Air Sampling Network data. A procedure has also been developed for determining the lint content of collected dust.

It has been experimentally demonstrated that airflow through filters can be expressed by the empirical relationship, v equals kAp super n, where v is face velocity, A is filter area, p is pressure drop across the filter, n is constant having a value less than unity, and k is a parameter which varies with the amount and type of dust. This equation suggests a starting point for predicating roll filter performance from panel filter tests, and to predict the effect of changing air velocity, pressure switch settings, and type of dust on roll filter performance.

An analysis, of the relationship between roll diameter and the amount of filter on a roll has been made, comparing empirical data with calculations in which a roll filter has an archimedian spiral.

1.0548, AIR TREATMENT FOR ODOR CONTROL IN THE HOSPITAL
T.W. KETHLEY, Georgia Inst. of Technology, Engineering Experiment Station, *Atlanta, Georgia* 30332

The objective of the study is to determine the ability of air treatment systems employed in hospitals to remove from the air odorants originating intramurally and or extramural gaseous air pollutants. During the past year work has continued, evaluating components of air handling systems. The evaluation of dilution ventilation is an essential part of these studies. It has been determined that odorant compounds not only sorb or condense upon surfaces and subsequently desorb or evaporate, and thus are slowly removed by ventilation, but also that for many of these compounds even the aerial content is not reduced with the expected efficiency by dilution ventilation. This difference becomes greater with increasing molecular weight of the odorant compound. The practical consequence of this finding is that increasing volumes of fresh air, or equivalent fresh air will yield poor results in reducing levels of higher molecular weight odorants in hospital rooms.

1. AIR QUALITY

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0549, RESEARCH INITIATION - APPLICATION OF HIGH VOLTAGE ELECTRIC FIELDS TO THE REMOVAL OF SO2 AND NO2 FROM COMBUSTION EFFLUENT
M.J. MATTESON, Georgia Inst. of Technology, School of Engineering, *Atlanta, Georgia* 30332

This investigation involves a new method by which sulfur dioxide and nitrogen dioxide gases may be removed from industrial combustion effluent. A simulated combustion effluent will be studied where SO2 and NO2 are ionized while flowing through a high voltage, wire-to-cylinder electric field. The ions react with oxygen and water vapor in the gas stream to produce charged nuclei of sulfuric and nitric acid which grow in the humid atmosphere and are precipitated on the grounded cylinder. The efficiency of removal of SO2 and NO2 are to be determined as a function of the concentration, gas velocity, relative humidity, and electric field strength.

SUPPORTED BY U.S. National Science Foundation

1.0550, REDUCTION OF ATMOSPHERIC POLLUTION BY THE APPLICATION OF FLUIDIZED-BED COMBUSTION
A.A. JONKE, Argonne National Laboratory, *Argonne, Illinois* 60439

Objective: To study the fluidized-bed combustion process as a method for reducing atmospheric pollutants.

Description: This program is concerned with a study of fluidized- bed combustion (FBC) as a method of reducing the quantity of atmospheric pollutants (oxides of sulfur and nitrogen) released during the combustion of fossil fuels. Basic and fundamental reaction kinetics and mechanisms of the SO2-limestone reaction are being investigated. A six- inch diameter FBC is being used to identify and study the principal factors affecting SO2 removal.

1.0551, A MODEL FOR AIR POLLUTION CONTROL
R.E. KOHN, Southern Illinois University, Graduate School, *Carbondale, Illinois* 62901

There is no single measurement of air quality as such. Air pollution is an overall category including individual pollutants such as aldehydes, carbon monoxide, hydrocarbons, nitrogen oxides, sulfur oxides, particulates, benzo(a)pyrene, etc. Since control methods usually affect more than one pollutant and sometimes increase some while decreasing others, a multi-pollutant model is required to determine an efficient set of control methods. Linear programming can be a useful vehicle for the multipollutant model.

Generally, linear programming models are static, optimizing for a specific year. However, air pollution control requires long-run considerations. The solution for any one year, if implemented, restricts the choice of control alternatives for future years. This project considers the implementation of a dynamic model. Such a model can suggest optimal long-run strategies for air pollution control, assess the significance of technological advancement in abatement, and be useful in providing the pollution parameters for solving the growing problem of solid waste disposal.

The site of this research is the St. Louis airshed, the most thoroughly investigated area in the United States as far as air pollution is concerned. Not only is a great amount of data from past studies available, but the fact that air pollution regulations have already been passed makes industry leaders much more communicative on the subject of control technology.

SUPPORTED BY U.S. National Science Foundation

1.0552, CONTROL OF PARTICULATE EMISSIONS FROM GASOLINE ENGINES
M.R. JACKSON, I I T Research Institute, *Chicago, Illinois* 60616

This project will continue two experimental programs which will establish the feasibility of developing high efficiency devices for removal of particulate matter from internal combustion engine exhausts.

The first approach is based on sonics glomeration in a fluidized bed. Theoretical considerations suggest that the power density requirements can be substantially reduced by sonic agglomeration in a fluidized bed of relatively larger particles.

The second technique makes use of the phenomenon of particle migration in a temperature gradient. Particle migration and deposition will be maximized by the sharp temperature gradients and small migration distances in a cold bed of packed particles. Relatively cool ambient air will be used to cool the bed, resulting in a cyclic operation of alternately heating and cooling the bed.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0553, STUDY OF PETROGRAPHIC AND MINERALOGICAL CHARACTERISTICS OF CARBONATE ROCKS RELATED TO SULFUR OXIDE SORPTION IN FLUE GASES
R.D. HARVEY, State Geol. Survey, *Urbana, Illinois* 61801

Selected carbonate rocks will be subject to detailed petrographic, mineralogical, and chemical analyses to determine what effect these parameters have on the capacity and rate of SO2 sorption. This project is to run concurrently with full-scale injection tests at TVA coal-fired power plants in Kentucky. Examination of the rocks considered and selected for injection into boilers as well as reacted products will be conducted during the course of this project. An automatic image- analyzing microscope system will be used to determine the crystalline- particle and pore-size distributions of the carbonate-rock samples. Petrographic examination will be supplemented with scanning electron-microscope observations. Complete chemical analyses will be obtained including trace-element analyses utilizing neutron-activation techniques.

SUPPORTED BY Illinois State Government - Springfield

1.0554, DETERMINATION OF MASS FLOW AND CONCENTRATION OF SUSPENSIONS
S.L. SOO, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

Accurate measurement of fuel flow in pulverized fuel lines is studied for better heat rate computations. Incorporation of a fuel flow signal in feed-back control systems will lead to significant improvement in the performance of pulverized fuel units. Study is made with an electrostatic probe. Measurement of dust concentration in stack gas is studied to determine a dependable means for the purpose of air pollution control on large steam generators.

SUPPORTED BY Detroit Edison Company

1.0555, FUNDAMENTAL STUDIES ON THE PROCESS FOR REMOVING NOX FROM FLUE GASES
R. KUMAR, Indian Inst. of Science, *Bangalore, India*

Description: The capability of the lime/limestone wet scrubbing process for the control of NOx and the effect of the presence of nitrogen compounds on the SOx removal efficiency are to be studied in the laboratory in a bench scale system. The chemistry, mechanism of reactions and kinetics of the heterogeneous gas-liquid-solid system involving the following problems are to be investigated; (a) gas phase interactions of NO, NO2, SO2, O2, and CO2, (b) liquid phase interactions of HSO3, SO3, SO4, NO2, NO3 with each other and NO2, SO2, and O2, and (c) effectiveness of different alkaline solutions for scrubbing NOx from flue gas.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0556, STUDY OF MECHANISM FOR INCREASING THE SOLUBILITY/HYDRATION OF LIME/LIMESTONE IN THE WET SCRUBBING SYSTEM FOR SOX CONTROL
R. KUMAR, Indian Inst. of Science, *Bangalore, India*

Description: The overall efficiency of SOx in the wet scrubbing process has been found to depend mainly on the hydra-

tion and dissolution of lime in the slurry hold tank. The present task will investigate the conditions under which an increase in solubility may be achieved. The use of additives, precipitation and dissolution mechanisms, effect of fluid dynamics and alterations in the design of slurry hold tank and recycling-system will be studied in detail. Correlations between operating conditions and hydration dissolution rate will be derived.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0557, CONTROL OF NOX EMISSIONS FROM AIRCRAFT GAS TURBINES
A.M. MELLOR, Purdue University, School of Mechanical Engin., *Lafayette, Indiana* 47907

Continue research presently in progress under sponsorship of Army Tank-Automotive Command, but scheduled to be terminated because of budgetary problems. The study will develop computer simulation techniques to aid in prediction of NO formation in gas turbine combustors at high inlet air temperatures. It will also conduct experimentation in single combustor facilities to verify the computer predictions.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0558, SMOG ELIMINATION RESULTING FROM BUILDING DESIGN AND CITY PLANNING
G.M. PALMER, Purdue University, School of Aeronautics, *Lafayette, Indiana* 47907

To study experimentally the effect of building design, building placement, and overall city layout on minimizing the smog accumulation potential of metropolitan areas by significantly reducing the critical wind velocity needed to purge areas of emission concentrations.

The above will be accomplished by scale model parametric studies of city arrays in a smoke tunnel. The basic model and the more promising innovations will be built on a larger scale and exposed to a scaled velocity--altitude wind profile in a large subsonic wind tunnel at varying wind directions from 0 degrees to 360 degrees or asymmetric fraction thereof. Observations will be made by eye and stop-motion movie camera of the effect on smoke introduced at judiciously chosen points. In addition, measurements of local velocities will be made by means of a hot film anemometer in an effort to quantify results.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

1.0559, CONTROL OF AIR CONTAMINANTS IN THE HOME
P.J. ANNIS, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN00691)

OBJECTIVE: Determine the effects of hood geometry, hood-range relationship, and hood air flow rate upon airborne contaminant capture efficiency. Determine whether: Vacuum cleaning causes appreciable amount of settled dust to go into suspension, this dust differs in size and character from that normally in suspension, this dust behaves as normal atmospheric dust while in suspension, vacuum cleaner design has an effect upon these variables.

APPROACH: Using mock-up hoods, geometry, location and air flow will be varied and each combination tested for efficiency in solid aerosol and water vapor removal. Atmospheric dust in several homes will be sampled to ascertain the problems in determining dust concentration level. Periods immediately before and after vacuuming and while using several styles of vacuum cleaners will be studied. Samples would be taken on MSA 1106 BH glass-fiber paper using a Gelman No 13200 carbon- ring, pistontype portable vacuum pump. Later, samples would be taken on type AA Milipore filters, from which size analyses can be determined by the MSA-Whitby method.

PROGRESS: The Effects of Range Hood Geometry, Location and Air Flow on Cooking Contaminant Removal. Data from 240 water vapor removal tests have been analyzed. Recommendations are being made for construction, location and usage of vented and unvented range hoods. Previous work with solid aerosols has been reviewed and additional testing with fluorescent tracers begun. The Effect of Vacuum Cleaning Upon Household Atmospheric Dust. Earlier work established that vacuum cleaning was a serious source of household atmospheric dust was followed by experiments measuring the filtration efficiency of various vacuum cleaner bags. A set of tests employed four bags, two vacuum cleaners, two laboratory residences and two types of occupancy periods. The test dust was that naturally occurring on carpets in the residence. The door openings, rug passages and rainfall were monitored to evaluate experimental control. Simultaneously, laboratory measurements enabled calculation of the two correlation parameters, the effective fiber size and filter solidarity factor, which have produced the best means of predicting filter performance. Statistical analysis of the data, to date, has shown one bag to be distinctly better than the others.

SUPPORTED BY Kansas State Government - Topeka

1.0560, ODOR REMOVAL FROM AIR BY ADSORPTION ON CHARCOAL
B.G. KYLE, Kansas State University, Graduate School, *Manhattan, Kansas* 66502

Description: The contract is expected to accomplish the following: a) Development of suitable experimental techniques so that reliable adsorption equilibrium and kinetic data may be obtained; b) Provide data for several homologous series of adsorbates; c) From data gathered and analyzed, acquire an understanding of the thermodynamics and kinetics of adsorption at low adsorbate concentrations.

The data and conclusions resulting from this study will be useful in the development of package adsorption devices for industrial odor control.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0561, SHOCK STABILITY OF BACKUP SUBMARINE ATMOSPHERE CONTROL COMPONENTS
R.B. CAREY, U.S. Navy, Ship Research & Dev. Lab., *Annapolis, Maryland* 21402

Technical Objective: Determine the ability of oxygen (O2) candles and lithium hydroxide (LIOH) canisters to perform their intended end use after being subjected to shock and vibration.

SUPPORTED BY U.S. Dept. of Defense - Navy

1.0562, PROTOTYPE STUDY OF LIMESTONE SCRUBBERS FOR SO2 DUST REMOVAL SYSTEMS - PHASE IIA EXTENSION
I.A. RABEN, Bechtel Corporation, *Gaithersburg, Maryland* 20760

Objective: Complete design of test program for Shawnee test facility.

Description: Planning and design of the test program for NAPCA's limestone-wet scrubbing test facility at TVA's Shawnee Station will be completed under this extension of Phase II A. The work remaining to be done includes portions of the following tasks:(1) simulation and evaluation of screening experiments using process models, (2) development of data handling and analysis manual; (3)design of the primary experiments, and (4) preparation of a test program manual.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0563, SO2 AND NOX REMOVALS FROM STACKS GASES BY CO
W.L. SHORT, Univ. of Massachusetts, School of Engineering, *Amherst, Massachusetts* 01002

In the second year of AP 00791 experimental results were obtained that indicated complete removal of SO2 by catalytic reduction with CO can be achieved at temperatures greater than 800 degrees F, at stoichiometric ratios of CO/SO2 and with contact times of O.05 to O.2 seconds. The best catalyst, chosen from the several tried was copper supported on alumina. There is a side reaction between the elemental sulfur formed from the reduction of SO2 and CO to produce COS. This side reaction has limited the total sulfur removal (SO2 plus COS produced) to about 70%. The

progress report discusses the techniques to be explored to overcome this problem.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0564, CONTROL TECHNIQUES FOR POLYCYCLIC ORGANIC MATTER

R. FOX, G C A Corporation, *Boston, Massachusetts*

Mail 1st draft to in-house and 3 review committees by August 1970. Revise into 2nd draft according to review comments, and submit final revision to OTIP for editing and publishing.

1.0565, RECOVERY OF NITROGEN AND SULFUR OXIDES FROM BOILER FLUE GASES

A. GRUBER, Tyco Laboratories Incorporated, *Boston, Massachusetts* 02154

Description: The work would include: (1) the operation and parametric study of the Tyco process, using a 'mini-plant' with 10 SCFM flue gas capacity; (2) the preliminary design of a 2,000 SCFM pilot plant; and (3) the development of improved NOx analytical and control techniques of the Tyco process.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0566, CRITERIA FOR DESIGN AND CONTROL OF INCINERATORS

A.F. SAROFIM, Mass. Inst. of Technology, School of Engineering, *Cambridge, Massachusetts* 02139

A number of design and operating variables will be investigated in an attempt to find a variable which can be related to the residue quality and which can be used to activate corrective action when the unburned fraction of the residue or in the stack gases becomes excessive. Included in these variables are excess air, fraction of air overfired, longitudinal distribution of air above and below the grate, air preheat, refuse bed height, and grate speed.

An experimental study of combustion will be made on a stationary fuel bed simulating a section of a traveling-grate stoker. Detailed measurements will be made of compositions and temperatures in and above the burning fuel bed in addition to infrared transmittance across the top of the bed. Concurrently, a semi-empirical mathematical model will be designed to extrapolate existing data to new conditions of operation or design so that adjustments can be made to incinerator operating conditions to accomodate changes in refuse quality.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0567, RESEARCH INITIATION - RATES OF SORPTION OF MOLECULAR SIEVES IN MULTICOMPONENT SORBATE SYSTEMS

Y.H. MA, Worcester Polytechnic Inst., Graduate School, *Worcester, Massachusetts* 01609

In this research constant volume techniques will be employed to obtain sorption rate data and sorption isotherms for gas mixtures on various molecular sieves. Data on sorption rate and sorption isotherms will be obtained for carbon dioxide, sulfur dioxide, and carbon monoxide on various commercial as well as specially synthesized zeolitic materials. Experimental studies will be conducted in a well-stirred reactor. The rate will be measured by either introducing the system which is already filled with 'inert' gas. Analyses of samples obtained from the well-mixed phase will be obtained by gas chromatography. The results of the study should find applications not only to the immediate problem of catalyst evaluation but also the evaluation of sorbent materials for removal of pollutants from exhaust gases.

SUPPORTED BY U.S. National Science Foundation

1.0568, NEW INORGANIC MATERIALS FOR SULFUR OXIDE REMOVAL

L.B. SAND, Worcester Polytechnic Inst., School of Engineering, *Worcester, Massachusetts* 01609

The objective of the project is the molecular engineering of porous inorganic materials, principally molecular sieve zeolites, which will perform selectively as sorbents in the removal of sulfur oxides and other noxious gases in effluent released to the atmosphere.

For the study, samples of every commercially available molecular sieve zeolite have been obtained either in powder or particulate form from the major suppliers, and a field trip was made to the western United States to obtain samples from deposits which have potential use in this application.

Three types of sorption equipment are in use on the project: a mechanical constant volume balance for rapid screening of porous materials, a manometer-reading constant volume glass apparatus (in duplicate) for the second stage of evaluation, and a quartz microspring balance with a Baratron pressure meter for final data accumulation. Comparative data have been obtained on sorption capacities for SO2, rates of sorption, and stability in a sulfuric acid system. All zeolites evaluated sorbed SO2 rapidly in amounts up to 35 wt. % (faujasite) and in direct proportion to their pore volumes. Mordenite (24 wt. % capacity) was found to be most acid stable. Current research is on particulates and the SO2-H2O sorbate system at simulated operating conditions.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0569, ADSORPTION RATE STUDIES - AIR POLLUTION

I. ZWIEBEL, Worcester Polytechnic Inst., School of Engineering, *Worcester, Massachusetts* 01609

It is expected that separations by adsorption will provide wide applications for packed-bed systems in combatting air pollution. Several processes have been developed for the cleaning of stack gases by such technique such as the removal of SO2 by the Reinluft Process and the Alkalized Alumina Process. However, currently, the economics of widespread implementation appear unfavorable because the necessary data and knowhow are lacking. In the design of such equipment the equilibrium phenomena are of paramount importance. Together with the rate criteria they determine the dynamic behavior of the process, and thus influence the sizing of the equipment, which in turn may economically make or break the operation. Furthermore, the coadsorption of several adsorbates, or the relative selectivity of the adsorbent for the various species in the gas, determine whether or not a desired separation is feasible.

It is felt that the most serious shortcoming of the past analyses is due to the restriction of the one-component isotherms. The purpose of the current project is to obtain the desired data with a high degree of accurary to satisfy the needs of a sophisticated design model. The adsorption properties of multicomponent systems of several gas mixtures consisting of O2, N2, SO2, CO2, H2O, CO, H2S, NH3, using a variety of adsorbents, will be measured. The behavior of the system will be observed to enable conclusions regarding the mechanism of adsorptions, interactions between species, and the energetics of the process. The results will be correlated with existing equilibrium equations as well as with the thermodynamic functions derived from Gibbs' relationship and the two-dimensional equations of state.

1.0570, EVALUATION OF EMISSION CONTROL SYSTEMS FOR EXISTING VEHICLE

H.L. GOMPF, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ann Arbor, Michigan* 48103

Those devices or techniques that are being publicly promoted as being suitable for retrofit on used cars are evaluated to determine their emission control effectiveness, their influence on vehicle performance and driveability, and their potential impact on vehicle operating costs. This information is required to be responsive to inquiries received by NAPCA from Federal, State, and local agencies concerning such devices. The level of effort planned for FY 71 is based on the assumption that there will be no Congressional action which directly involves NAPCA in used venicles. Should such legislation be passed, the level of effort would be approximately quadrupled.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0571, TEST EVALUATION REPORT COVERING PAST UNPUBLISHED CONTROL DEVICE EVALUATION TESTS
H.H. HOPKINS, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ann Arbor, Michigan* 48103

A large number of in house tests conducted by NAPCA over the past years have not been reported in a form which could be widely distributed. This task will provide funding and assistance to a contractor to prepare a report in which all such tests will be listed including descriptions of devices tested and results achieved.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0572, CONTROL OF CO AND HC EMISSIONS FROM LIGHT AIRCRAFT AND OTHER NON-REGULATED MOBILE SOURCES
B.D. MCNUTT, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ann Arbor, Michigan* 48103

This project will follow up present tests on light aircraft emissions and initiate investigation of methods for control of emissions from this source, considering modification in flight procedures and in powerplant accessories.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0573, DEVELOPMENT OF IMPROVED NOX CONTROL FOR DIESEL ENGINES
S.L. QUICK, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ann Arbor, Michigan* 48103

The contract will cover the development of one new nitrogen oxides control system to the point permitting detailed experimental evaluation in a vehicle.

The system chosen will be applicable to either or both spark ignition and diesel powerplants and will be based on research presently being started under several FY 70 contracts.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0574, DIESEL EMISSION CONTROL
R.C. STAHMAN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ann Arbor, Michigan* 48103

Control devices and fuel additives are screened using laboratory smoke and odor test techniques developed early in this continuing program. The more effective controls are fleet tested for period of at least six months to determine their effectiveness with time and mileage accumulation under typical fuel conditions. Fleet test vehicles are periodically returned to the laboratory for smoke and odor tests. Concurrent with these tests, chemical analyses of diesel exhaust are made for correlation against odor readings.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0575, EVALUATION OF EMISSION CONTROL SYSTEMS FOR NEW VEHICLE
J.C. THOMSON, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ann Arbor, Michigan* 48103

Those devices and techniques that are being publicly promoted as having capability of meeting 1975 and later standards are evaluated to determine the validity of such claims, to assess the state of the art emission control technology, and to support standard setting. Such systems are generally supplied NAPCA at the developer's expense but where it is warranted, the government would provide a control for the developer to bring the control system to Government laboratories and assist in operation of the system during evaluation.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0576, TESTING OF EMISSION CHARACTERIZATION AND CONTROL PROJECTS
J.C. THOMSON, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ann Arbor, Michigan* 48103

Tests will be run as requested to provide evaluation of control devices or techniques which are products of the Emission Characterization and Control Branch. Emission characterization studies will be made where NAPCA facilities and analytical procedures can provide the repuired information.

1.0577, LOW EMISSION ULTRABAN PISTON
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ann Arbor, Michigan* 48103

Development of a stratified charge engine applicable to passenger car.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0578, CATALYTIC MEDIA TO REDUCE NOX EMISSIONS FROM GASOLINE
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ann Arbor, Michigan* 48103

Investigate new catalytic media for elimination of NOx emissions from gasoline engine exhaust.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0579, FUEL INJECTION
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ann Arbor, Michigan* 48103

Experimental determination of the maximum nitrogen oxides control achievable with an existing fuel injectionn system.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0580, REDUCTION OF EMISSION CONTROL SYSTEM DEGRADATION
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ann Arbor, Michigan* 48103

Determine the potential for and aid the development of high-durability, engine related components to minimize emission control system degradation.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0581, INVESTIGATE NON-CARBGNACEOUS ALTERNATIVE FUELS FOR CONTROL OF EMISSIONS
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ann Arbor, Michigan* 48103

No summary has been provided to the Science Information Exchange.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0582, CARBURETORS - REDUCTION OF EXHAUST EMISSIONS
J.A. BOLT, Univ. of Michigan, School of Engineering, *Ann Arbor, Michigan* 48106

This proposal is concerned with the reduction of undesirable exhaust emissions from automotive engines. The most important single factor affecting the quantity of undesirable exhaust emissions from gasoline engines is the fuel/air mixture ratio. The carburetor establishes this mixture ratio delivered to the engine cylinders. In general, the use of a lean mixture (more excess air) will result in a reduction in the emissions. It is therefore important to develop engines capable of using the leanest possible mixture ratio, and to have carburetors that deliver this mixture as precisely as possible under all conditions.

This PHS project AP00365 is concerned with evaluating the sources of metering error in present carburetors, and with means

for reducing these errors, and includes the following: (1) Further evaluation of the effect of variation of commercial gasoline properties on carburetor metering, and efforts to reduce these errors, (2) to develop a computer simulation of an automotive carburetor, which will require additional experimental data. This simulation will lead to greater understanding of the complex flow phenomena involved, permit further study of variables which affect carburetor metering accuracy, and hopefully will demonstrate to industrial carburetor engineering groups the merits of more analytical techniques than they have used for the design of carburetors, (3) study and simulate the effect of pressure pulsation upon carburetor metering characteristics, (4) determine the influence of some variables on the leanest practical mixture ratio of engines, for example, the advantages of preheating the engine inlet air.

This type of work is presently carried on with graduate students and results in more men being educated in this area of engineering.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0583, FUEL INJECTION SYSTEM ANALYSIS - DIESEL SMOKE REDUCTION

J.A. BOLT, Univ. of Michigan, School of Engineering, *Ann Arbor, Michigan* 48106

This proposal is concerned with the reduction of smoke from diesel engine exhaust, especially as affected by the fuel injection system characteristics.

Our experience and research work with experimental and production diesel engines at the University of Michigan, and the experience of others expert in this field, has convinced me that important reductions in exhaust smoke could be accomplished if the engines had better fuel injection systems. For example, my observation, confirmed by many diesel engine research men, indicates that many diesel engines produce unnecessary smoke because the injection systems have line pressure waves which cause the fuel injection nozzles to inject a secondary fuel quantity after injection is normally completed. This program is aggravated by the fact that supercharging of diesel engines requires that the range of fuel flow from idle to maximum power be greatly increased.

We have developed a mathematical model which accurately simulates the hydraulic phenomena of a typical diesel fuel injection system. With this computer tool efforts are being made to identify design changes of the injection system which will improve the nozzle fuel spray characteristics.

The merits of such improved, or different, systems will be evaluated on one of our research engines. This will include measurement of the smoke and exhaust emissions.

1.0585, HYBRID COMBUSTION PROCESS (FCP) APPLICATIONS FOR MILITARY VEHICLES

A. SIMKO, Ford Motor Company, *Dearborn, Michigan* (DAAE07)

Technical objective: The technical objective is to lower fuel consumption in military vehicles through better combustion at part load operation. An additional objective is to reduce air pollution. The technical question being explored is whether efficient, low emissions combustion and acceptable durability can be achieved in an internal combustion hybrid engine. The hybrid combustion process will have direct application for improvement of all engines used in military vehicles. The performance goals are to reduce fuel consumption by 30-40 percent with no loss in performance and to drastically reduce undesirable exhaust gas pollutants to meet 1975 federal standards.

SUPPORTED BY U.S. Dept. of Defense - Army

1.0586, MATERIALS HANDLING, COLLECTION AND DISPOSAL IN THE MID-SOUTH AREA

O.L. MCCASKILL, U.S. Dept. of Agriculture, Agricultural Engineering Div., *Stoneville, Mississippi* (308-035-C115)

OBJECTIVE: Conduct tests to identify the gin trash emission problem and develop a more efficient system of receiving seed cotton at the gin, gin trash collection and disposal, and packaging lint cotton.

APPROACH: Conduct tests in a commerical size plant, determine the air emission characteristics and problem at cotton gins handling machine picked cotton. Test and adapt commercially developed air pollution abatement equipment into a system which will meet the various state air quality standards for cotton gins. Based on previous studies, develop and test a packaging system for lint cotton which would require a minimum of power and supervision at the gin, lend itself to simplified handling procedures in the channels of trade and easily handled, opened and blended at the mill. Develop a system for receiving cotton at the gin utilizing a method being developed by others for transporting the material from the harvester.

PROGRESS: An experimental roller-dropper shows some promise for improving efficiency. The number of rollers and thickness of the lint batt, not the roll pressure, is significant in batt compression. The use of precompression rollers on the lint slide had no effect on bale density. Air volume has a significant effect on cyclone operating efficiency. Feed rate has no effect on cyclone efficiency. Interaction of feed rates and operating air volume affect dust concentration in the cyclone exhaust. An experimental bale forming system was redesigned, fabrication has been completed, and assembly is underway. At a ginning rate of 10 bales per hour on machine-picked cotton, an average of 13.5 pounds of dust per hour will be emitted from cyclone and condenser exhausts. Cyclone emission was 1.3 and condenser emission was 12.2 pounds per hour.

SUPPORTED BY U.S. Dept. of Agriculture

1.0587, COTTON LINT HANDLING AND PACKAGING AND TRASH COLLECTION

V.P. MOORE, U.S. Dept. of Agriculture, Agricultural Engineering Div., *Stoneville, Mississippi* (308-035-C107)

OBJECTIVE: Develop low-cost methods for unloading and conveying seed cotton and its components, and collecting, packaging, and disposing of materials incident to ginning.

APPROACH: Investigate commercially available filter principles for possible use or adaptation for use in gins. Investigate the possibility of modifying standard condensers to perform the dual purpose of filtering the air as well as their normal function. Undertake development of a complete trash and dust collection system which can meet standards for air pollution. Investigate new methods and equipment for packaging cotton with major emphasis given to forming a picker lap-like package.

PROGRESS: The prototype of a new packaging system was tested and indicated modifications are underway. A commercial skimmer showed promise as a primary collector of gin trash which does not contain lint. A second year's test results show that there is considerable variation in the amount of particulate matter in the atmosphere at given distances downwind from a gin. Efforts to develop prediction equations have been unsuccessful. Tests of cyclone design indicated that the conventional Atomic Energy Commission design was more efficient for the collection of fine dust than one having an envolute entrance.

1.0588, SYSTEMS STUDY OF NITROGEN OXIDES CONTROL METHODS FOR STATIONARY SOURCES
W. BARTOK, Standard Oil Co. of New Jersey, *Linden, New Jersey* 07036

Description: The purpose of this study is to obtain needed additional data on nitrogen oxides formation, sources, and control techniques to assist NAPCA in evaluating, and executing the appropriate research and development program to make available control technology for nitrogen oxides. This work will extend and supplement the information obtained in the first phase. The specific work functions include: 1) acquisition of NOx emissions data from existing power plants, 2) develop mathematical models and conduct lab experiments for NOx formation, and 3) design experimental test programs for modifying and testing utility-scale boilers for lower NOx formation.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0589, FUEL MODIFICATION FOR ABATEMENT OF AIRCRAFT ENGINE EMISSIONS
A. SKOPP, Standard Oil Co. of New Jersey, *Linden, New Jersey* 07036 (F33615-71-C-1575)

Technical Objective: Determine whether or not fuel modification is a feasible approach for significantly reducing the oxides of nitrogen (NOx) emissions of aircraft gas turbine engines. Fuel modification means any treatment, including the addition of catalytic or other agents, that results in a slight change in fuel composition.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0590, CONTROL OF ETHYLENE-INDUCED SEPAL WILT OF ORCHIDS
O.W. DAVIDSON, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00244)

OBJECTIVE: Study control of sepal wilt of orchids demonstrating that traces of ethylene can be successfully removed from a polluted air supply by drying that air and then passing it through brominated activated carbon.

APPROACH: Revise equipment to permit accurate determination of the permissible moisture content of the filtered air. Simplify the mechanical equipment.

PROGRESS: Work on this project was terminated in June of 1968. This investigation has demonstrated that traces of ethylene can be removed from a polluted atmosphere by means of filtration through brominated, activated carbon. Factors limiting the reaction between trace amounts of ethylene and brominated carbon, including degree of bromination, and the temperature relative humidity and residence time of the filtered air have been studied, and the extent of influence of these factors established. Also investigated was the maintenance requirements of the equipment used, including methods for recharging the filters while in operation. A manuscript is being prepared to cover the results of this investigation, and it will be completed this spring. Subsequently the endogenous production of ethylene by orchids and other flowers has been studied. This work has demonstrated the evolution of ethylene in responses to pollination by all species studied.

SUPPORTED BY New Jersey State Government - Trenton

1.0591, COTTON MATERIALS HANDLING AND AIR TRASH SEPARATION
V.L. STEDRONSKY, U.S. Dept. of Agriculture, S.W. Cotton Ginning Res. Lab., *Mesilla Park, New Mexico* 88047 (308-037-C108)

OBJECTIVE: Develop low-cost methods for unloading and conveying seed cotton and its components, and collecting and disposing of materials incident to ginning.

APPROACH: Continue modification of a commercial air flotation conveyor for moving various materials during the cotton ginning operation. Adapt the laboratory-developed inline filter for use in conjunction with a moisture restoration system previously developed. Study additional methods of air-trash separation in an effort to devise alternate means for meeting air pollution standards.

PROGRESS: A hopper feeder was designed to receive seed cotton from a farm trailer. It handled loose cotton and cotton compressed to a density of 12 pounds per cubic foot satisfactorily. Cotton which was tramped in the hopper bridged above the feed mechanism. A commercial inertial air cleaner was found to be 80 to 90 percent efficient in collecting material which emitted from the exhaust of a cyclone handling gin trash. A 90 degree elbow at the inlet of a cyclone causes the cyclone to lose twice as much dust as when it is fed from a straight pipe. To eliminate the efficiency loss, elbows should be at least 10 pipe diameters from the cyclone. Back pressure on a cyclone was found to be highest when handling air only. There was a 25 percent drop with the same air volume when trash began entering it.

SUPPORTED BY U.S. Dept. of Agriculture

1.0592, CLOSED LOOP FILTERING SYSTEM FOR USE IN COTTON GINS
V.L. STEDRONSKY, U.S. Dept. of Agriculture, S.W. Cotton Ginning Res. Lab., *Mesilla Park, New Mexico* 88047 (308-035-C114)

OBJECTIVE: Evaluate various types and combinations of experimental and commercial filtering equipment incident to the design of a closed loop moisture conditioning system for use in cotton gins and the use of condenser covering having small openings on the quality of cotton.

APPROACH: Using as a basis, the high efficiency cyclone and the in-line filter, combinations of filtering equipment will be devised for the various types of foreign matter discharged from the several processing steps in the plant. If the foregoing filter combinations do not prove to be adequate, airwash or additional dry types of filters will be added to the combination to prevent particulate matter buildup in the system as the air is cleaned and transferred from one process to another in the plant. Particulate matter will be measured by conventional means. A plant will be equipped with conventional and experimental condenser drums and direct comparison of the grade and fiber properties will be made of the lint from the two ginning conditions.

PROGRESS: An inertial air cleaner proved to be 43 percent efficient in handling fine dust following two sets of cyclones. A mechanical telescope with the lip pulsating at 600 cycles per minute increased feed rate 27 percent and reduced power requirements by 27 percent. A condenser covered with 70 mesh screen emitted 32 percent less particulate matter than with the conventional covering.

1.0593, HYBRID COMBUSTION PROCESS (TCP) APPLICATION FOR MILITARY VEHICLES
E. MITCHELL, Texaco Incorporated, *Beacon, New York* 12508 (DAALO7)

Technical Objective: Research objective is to lower fuel consumption in military vehicles through better combustion at light-load operation. Additional goal is to reduce air pollution. The technical question being explored is whether efficient low emissions combustion can be achieved in internal combustion engine. The combustion process will have direct application for improvement of all future engines used in military vehicles. The performance goals are to reduce fuel consumption by 30-50 percent with no loss in performance and to drastically reduce exhaust gas pollutants to meet 1975 federal standards.

SUPPORTED BY U.S. Dept. of Defense - Army

1.0594, PILOT PLAN STUDY OF LIMESTONE-WET SCRUBBING IN A TURBULENT CONTACT ABSORBER
UNKNOWN, Babcock & Wilcox Company, *New York, New York*

Objective: Test the effect of major design and operating variables on SO2 removal for a limestone-wet scrubbing process.

1. AIR QUALITY

Description: This project consists of experiments on a coal-fired furnace connected to a scrubber pilot plant. The pilot plant comprises both a venturi-cyclone scrubber unit and a turbulent contact absorber (TCA) unit. Testing of the pilot plant will include investigating the effects of reactant type, coal type, inlet, flue gas temperature, gas- liquid contact time, scrubber type, use of ash alkalinity, and degree of CaSO3 oxidation. Results of this program will support the testing planned for the TVA, Shawnee test facility.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0595, FILTRATION OF AEROSOLS BY GRANULAR BEDS

A.M. SQUIRES, City University of New York, School of Engineering, *New York, New York* 10031

The immediate objective of the proposed research is to learn the mechanics governing the formation and retention of a filter cake of power station fly ash on a 'free' surface of a granular solid--i.e., a surface retained at substantially the angle of repose of the solid. Viewed more broadly, the objective is to understand the factors which govern the fly-ash collection efficiency of a 'panel-bed' filtration device treating power-station stack gases--i.e., a device in which the gases flow across a tall, narrow bed of granular solid retained between two parallel, vertical, perforate walls--the gases entering the bed via free surfaces on which filter cake forms. In the practical operation of such a device, the filter cake together with a small amount of the granular solid is removed periodically, thereby allowing new free surfaces to arise.

Another objective is that the research shall serve as an introduction to a program studying panel-bed filters for a variety of important dusts of industrial origin (such as iron-oxide fume and cement fines), studying the behavior of such filters at high temperatures, and studying their performance with the help of 'filter aids' (such as asbestos dust) and with granular solids carrying electrical charge.

1.0596, FUNDAMENTALS OF AIR CLEANING BY SORPTION PROCESSES

M.J. LOW, New York University, School of Arts, *New York, New York* 10003

Gaseous impurities in air streams may be removed by condensation processes during which the contaminant is converted to a liquid or solid and is thus removed from the air, or by solution processes, during which the contaminant is dissolved in a suitable solvent, or by gas-solid interactions causing concentration of the contaminant at the surface of a solid.

Of the methods available, the most generally useful are those involving gas-solid interactions such as physical or chemical adsorption. However, although some technological practice has become established for some aspects of air cleaning, gas-solid interactions are extremely complex, and the fundamental mechanisms involved are far from being understood.

A program of fundamental research on the mechanisms of gas-solid interactions is being carried out at New York University. Infrared spectroscopic techniques, including Fourier transform spectroscopy, are being used.

1.0597, REVERSIBLE METAL COMPLEXES WITH AIR POLLUTANTS

L. VASKA, Clarkson College of Technology, Graduate School, *Potsdam, New York* 13676

The principal objective of this research program is to develop economically feasible materials which would reversibly absorb some common air-polluting molecules and/or catalyze their conversion to non- volatile, harmless, and useful substances. The proposed research is based on the author's discovery of a series of metal complexes which combine reversibly with SO2, CO, NO, and a variety of related gases, and the subsequent development of a theory for the reversible activation of these molecules. Another objective is to gain insight into the physiological effects of air pollutants by using the reactions of the latter with metal complexes as model systems.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0598, DUST DEPOSITION AND RETENTION

P.E. MORROW, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)49)

The capacity of the respiratory system to eliminate normal secretions, macrophages and cellular debris, also serves to remove the constant influx of airborne contaminants of the particulate type. Until the advent of radioisotopes, this capacity was not subject to quantitative examination. At present, the several cleansing mechanisms serving the respiratory system are being investigated in our laboratories by the use of special 'tagged' aerosols whose behavior can be followed by external radiation counters. This approach, which is equally suitable to laboratory animals and to man, is also being examined as a practical way for evaluating pulmonary functions previously inaccessible in intact subjects, e.g., the movement of mucus in the bronchial tree. This potentiality has important implications in the study of pulmonary disease. The general approach is capable of supplying information relevant to pneumoconioses and experimental pulmonary pathology, providing new physiological and cytological data; and contributing to an essential activity of health physics and toxicology, the evaluation of airborne hazards.

RESULTS: Clearance studies with heterodisperse and monodisperse aerosols have been conducted in normal human subjects. Results indicate that both kinds of aerosols are useful for evaluating tracheobronchial clearance. A gradient of mucociliary velocities was verified ranging from 0.1 to approximately 1.5 cm/min. The clearance pattern of a given aerosol was found suitably reproducible although complex. In subjects with pulmonary abnormalities, differences from normal clearance patterns have been revealed. Recently the external counting system has been redesigned to provide greater sensitivity and versatility for future studies.

1.0602, GAS CLEANING PROCESS STUDIES
L.H. GARCIA, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Description: Bench scale gas liquid contactors (i.e., batch reactor, laminar jet absorber, and packed scrubber) will be used to investigate the absorptivity of NOx and other gases in aqueous solutions and slurries. Parameters such as L/G ratos, temperature, and recycle ratios will be evaluated. Mass transfer coeffifients and their dependence on Reynolds numbers will be measured. Kinetics of the reactions will be measured, mechanisms will be defined, and factors affecting the efficiency of removal of the specific pollutant gas under investigation will be evaluated.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0603, DESIGN OF WET SCRUBBING TEST FACILITIES
D.B. HARRIS, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

This task is for the design of two pilot scale test facilities for use in conducting in-house research activities at the new research facility in North Carolina. Two test systems, one for particulate control and one for odor control are to be designed. It would have maximum flexibility for unit testing and a high level of control will be maintained on test parameters to allow accurate testing and continuous monitoring of major parameters.

After completion of the design of these two test loops, they will then be installed during the last half of FY 71. Such scheduling means that the system would be available for testing at the time of relocation and research program interruption caused by the move and limited in- house personnel would be minimal, if any.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0604, PARTICULATE CONTROL STUDIES
D.B. HARRIS, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Description: A program to test the characteristics of control devices as particulate collectors has been underway. At the end of 1969, an extensive period of testing was complete with the first unit during which experimental procedures were developed. This test indicated an acute need for a system to adequately redisperse the test particulate. Meanwhile, DPCE priorities had changed and the system was converted to handle the study of sulfur dioxide-limestone wet scrubbing.

A development program will begin early in FY 71 to provide a system to study the redispersion problem. Literature and manufacturers will be surveyed to identify the present practices which can be used as a base for designing a unit to meet our needs. Testing will be accomplished with new particulate characterization equipment and monitoring the success of redispersing particulates. The particulate collection study will be reactivated. A test system will be constructed to continue the study of scrubbers as particulate collectors. Testing will continue through FY 72 on four additional collect-types. Advance particle characterization units will be added to the testing program during both years.

1.0607, CONTROL OF COMBUSTION CHEMISTRY - KINETICS AND CATALYST
G.M. MARTIN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To determine feasibility of controlling, NOx SOx, particulate emissions by altering the chemistry of combustion.

Description: This project will investigate the control of emissions from oil-fired combustion systems by modification of combustion kinetics or by catalysis. Existing information of the kinetics of formation on oxides of sulfur and nitrogen will be surveyed and applicable technology explored. Correlation of various fuel composition with combustion emissions and kinetics will be determined experimentally. Based on these technologies modification, the combustion kinetics will be evaluated as a control method.

Similar review of the literature will be made to obtain information which will lead to control of emissions through catalytic effects in the combustion flame. This information will be incorporated into a control program through catalysis. As a part of this investigation, the study of the effects of proprietary fuel additives on air pollutant emissions (particulate, SOx, NOx, CO, and HC) from oil fired combustion sources, especially residual oil, will be continued. In addition, pure organometallic compounds will be tested to provide fundamental data on the effects of metallic species on combustion. The relation-ship of fuel composition to additive effectiveness will also be investigated.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0608, ODOR CONTROL RESEARCH - COMPLETE KINETICS STUDY AND INITIATE SCRUBBER DEVELOPMENT
B.N. MURTHY, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Description: Simple odorous gases representing emissions from offensive industries are being treated with various reagents in a set of screening tests designed to select promising scrubbing reagents. Selected reagents will be subjected to detailed kinetic studies and a rate expression for each set based on an understanding of the reaction mechanism will be derived. Mass transfer effects and process and design variables will be studied in pilot scale test units for a set of six types of scrubbers. Optimum conditions will be used in the design of prototype units to be operated on actual industrial sites for demonstration and economic studies.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0609, APPLIED SCRUBBER RESEARCH FOR CONTROL OF SOX AND NOX
B.N. MURTHY, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Description: Design data needed for the design of the prototype lime/limestone and dolomite wet scrubbing system for SOx and NOx control are to be collected in a pilot scale scrubbing test system in-house. The following factors affecting effectiveness in

removal of SOx are to be studied. a) Mass transfer in the scrubbing section; b) Hydration, dissolution and chemical reaction rates of lime/limestone and reaction products in the slurry hold tank and the scrubber; c) particle size of recycling limestone; d) Physical and chemical characteristics of the limestone used; e) Type of scrubber used.

Results from the study will be analyzed to derive the required correlations between process variables and SOx absorption efficiency.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0610, CONTROL TECHNIQUES FOR BERYLLIUM EMISSIONS
J. PEOPLES, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Monitor contract and mail 1st draft to in-house and 3 review committees by February 1971. Hold review meetings with Advisory Committee and with Federal Agencies. Complete 75 percent of 1st draft revision by 6/71.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0611, PUBLISH NATIONWIDE EVALUATION OF AEROMETRIC DATA ON A REGIONAL BASIS FOR SPECIFIC POLLUTANTS
J. REAGAN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To summarize and make available aerometric data on an air quality control regional basis.

Approach: Brief summaries of Federal and non-federal air quality, emissions and related data are compiled and presented on an air quality control regional basis of SMSA basis. Statistics are augmented by brief interpretations of data.

Goal: Publish report on sulfur dioxide and particulates and a report on total oxidants, hydrocarbons and carbon monoxide.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0612, ARGONNE NATIONAL LABORATORY INTERAGENCY AGREEMENT
D. TYLER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Under interagency agreement with the Argonne National Laboratory the following will be developed: 1. Preparation of an incident control model operations manual that is applicable to all areas of the country. Such a manual has been prepared for the City of Chicago; the task here is to make this manual applicable to all regions. 2. Develop incident control modeling techniques that can be used by the EOCC to develop abatement strategies for episode-prone areas. 3. Develope new procedures for the operation of the EOCC designed to expand and improve its operation. An operations manual will be included. 4. Develop procedures by which the EOCC will respond to accidental episode situations resulting from industrial process accidents and spills.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0613, AIR QUALITY CONTROL SERVICE
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Continuing subsequently to the adoption of each 'NAPCA standard method', NAPCA laboratories using the method will be supplied carefully standardized materials or procedures as appropriate, and then analyses will be reported for recording on control charts derivation of standard deviations and assessment of accuracy. This will be a continuing operation to provide standards and procedures by which the standard deviation and accuracy of a laboratory's analyses may be determined. NAPCA, and State and local laboratories on a voluntary basis, will be served.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0614, EVALUATE CONTROL TECHNOLOGY APPLICABLE TO MOTOR VEHICLES AND STATIONARY SOURCES
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Independent evaluation of control technology applicable to motor vehicles and stationary sources in relation to the existing state-of- the-art as well as the projected state-of-the-art for the next 15-year period.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0615, COMPLETE EVALUATION OF STANDARDS FOR MOTOR VEHICLE FUEL COMPOSITION (INCLUDING ADDITIVES)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Federal legislation which provides for national emission standards restricts the Secretary's authority to the control of air pollution from motor vehicles and from Federal facilities. Federal standards, accordingly, are directed against the motor vehicle. There is considerable evidence that the control of air pollution would be furthered through the control of vehicle fuel composition and boiling point as well as additive content. Determination of the trade-offs in the effectiveness and costs between this avenue of control and direct control of emissions from the motor vehicle is required prior to requesting that Congressional authority for the control of motor fuels be given to the Secretary.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0616, COMPLETE FEASIBILITY STUDY OF EVAPORATIVE STANDARDS FOR THE MARKETING OF GASOLINE
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

HC emissions from the rate vehicles are being controlled to the point where evaporative losses associated with the marketing of gasoline may represent a significant fraction of the remaining HC emissions to the atmosphere. The cost effectiveness and control technology involved in the elimination of the source will be examined.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0617, AQCR ASSISTANCE - CONTROL STRATEGY
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Assist States in the development of the control strategy that will be used to meet the air quality standards. Such assistance will include the utilizaton of mathematical diffusion models needed to estimate reductions in pollutant emissions needed to attain ambient air quality standards.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0618, AQCR ASSISTANCE - EMERGENCY EPISODE PROCEDURES
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Assist states in the development of emergency episode procedures. This will include development of alert systems and procedures for the curtailment of specific industrial process, fuel combustion and incineration sources.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0619, SOME TRANSITION METAL CHEMISTRY AND STRUCTURES OF COMPLEXES INVOLVING TWO COMMON AIR POLLUTANTS
W.A. MCALLISTER, East Carolina University, School of Arts, *Greenville, North Carolina* 27834

The broad objectives of this project are to examine various transition metal carbonyl and nitrosyl compounds for their catalytic effectiveness in reducing NO and oxidizing CO to non-toxic gases. Included in this is the search for effective catalysts at low temperature. The bonding in these catalysts will be investigated and related to the measured catalytic effectiveness. The actual reaction of interest is: 2NO plus 2CO yields N2 plus 2CO2. Since both are present in combustion products this represents a real system.

Reactions are carried out in glass reaction systems with measured amounts of catalysts over reproducible temperature ranges. Analysis of the gaseous products are accomplished using a gas chromatograph. The bonding in the metal complexes used as catalysts will be principally examined using infrared, U.V.-visible, and Raman spectroscopy. Force constants and other bonding data will be obtained through standard calculations.

The relative reaction rates and the physical bonding data will be hopefully related in an obvious manner.

SUPPORTED BY North Carolina State Government - Raleigh

1.0620, INTERACTION OF FUEL AND ENGINE FACTORS INFLUENCING EXHAUST EMISSIONS
W.F. MARSHALL, U.S. Dept. of the Interior, Bureau of Mines, *Bartlesville, Oklahoma*

Purpose: To amplify and refine information showing the dependence of exhaust composition on fuel composition and on the primary factors that control combustion; in applying these findings, to show how fuel and engine factors are manipulated to best advantage in reducing objectionable air pollutants.

Method: Continue work with multifunctional fuel additives to control engine cleanliness and combustion-system deposits. Obtain emission data using vehicles and engines with prototype low-emission systems to provide information on emission levels attainable with each of the several systems and to make a comparative study of differing fuel formulations proposed for the systems. Continue experimental research using a single-cylinder engine to study fuel as a variable in combustion.

Achievements 1969-1970: It was found that the additives studied produced no significant effect on exhaust emissions. Two additives were intended to maintain induction-system cleanliness-- a nickel alkyl phosphate and an alkylaminoalkyl phosphate-- and one additive was designed to reduce lead salt deposits in combustion chambers-- a cresyl diphenyl phosphate. Experimental work involving a single- cylinder engine using pure hydrocarbons and simple mixtures of pure hydrocarbons showed that paraffin-aromatic and olefin-aromatic mixtures as fuel produced larger quantities of several alkylbenzenes and alkenylbenzenes than was produced by the aromatic used alone as fuel. Inlet mixture temperature had little or no effect on exhaust emissions when the temperature was varied from 160 degrees to 280 degrees F.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0621, EVALUATION OF METAL OXIDES AS SORBENTS FOR SO2 IN POWER PLANT FLUE GASES
H.J. KELLY, U.S. Dept. of the Interior, Bureau of Mines, *Albany, Oregon*

Description: This effort will evaluate metal oxide sorbents as offered by industry and private or government institutions. Such sorbent evaluation is oriented to generate sorption and regeneration rate data and to test a sorbent performance under solid gas contacting conditions deemed to be appropriate for a particular sorbent. In the process of the above sorbent testing, some development work on improving chemical and/or physical sorbent characteristics is possible.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0622, EVALUATION OF METAL OXIDES AS SORBENTS FOR SO2 IN POWER PLANT GASES
J.W. TOWN, U.S. Dept. of the Interior, Bureau of Mines, *Albany, Oregon*

The objectives have been redefined to cover a wider scope of sorbent research than encompassed in previous years. The development of sorbents for the removal of SO2 from coal combustion gas will emphasize carriers impregnated with metal oxide sorbents. Sufficient kinetic information will be developed to evaluate these systems in their application to air pollution control. The work will include development of a suitable carrier, methods of impregnation, evaluation of performance in both thin-bed sorbers and regenerators and by semi- continuous fluid-bed reactors. Physical stability of the sorbent also will be measured during the sorption-regeneration cycle. An additional phase of the research will be to evaluate sorbents prepared by industry.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0623, FIELD BURNING AIR POLLUTION ABATEMENT INVESTIGATIONS
D.O. CHILCOTE, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00883)

OBJECTIVE: Develop methods of crop residue incineration which minimize the emission and effects of smoke and maintain crop production and quality standards. Investigate alternate methods to field incineration for residue removal, field sanitation, seeding preparation, and physiological stimulation of crop yields. Investigate commercial utilization of crop residues including associated problems of densification and storage.

APPROACH: Crop residues will be burned under different atmospheric conditions in the field to determine the optimum for minimal pollutant emission, favorable smoke dispersal and maximum seed yield and quality. Measurements made of burning emissions, atmospheric parameters, soil and residue moisture, and temperatures during incinerations will be related to pollutant emission and subsequent seed yield and quality, stand longevity, pest incidence and control, and herbicide and fertilizer efficiency. Alternate methods to burning for residue removal including mechanical removal techniques, propane flaming, and combinations of these will be studied. Methods of crop establishment with and without residue removal will be investigated. Commercial utilization of crop residues and methods of densification will be evaluated.

PROGRESS: Demonstrated the benefits of burning early (August) on particulate emission and subsequent grass seed crop yield. Determined the need for removal of residue from seed fields and the relative yield reduction for various species from removal methods other than burning. Demonstrated propane flaming as a promising alternative to open burning. Seed yields are comparable to open burning. Costs are much higher. Assisted in the development of a formula to predict areas which could be burned in certain areas without causing reduced air quality depending on meteorological conditions. Evaluated backfiring of fields as a means of reducing pollutant emission. Results suggest better combustion does occur. Determined thermal treatment necessary to destroy weed seeds and effects of high temperatures and the burning process on grass plants. Determined that straw can be utilized as an animal feed and in paper making and participated in tests on micro-biological transformations of straw and straw as a source of cellulose for plastics. Expanded efforts on development of a field incinerator.

SUPPORTED BY Oregon State Government

1.0624, APPLICATIONS OF CRYOGENIC TECHNIQUES TO PROBLEMS IN AIR POLLUTION
R.J. DONNELLY, Univ. of Oregon, School of Liberal Arts, *Eugene, Oregon* 97403

Preliminary studies carried out at the University of Oregon indicate cryogenic trapping is an effective means for removing low level pollutants from energy production source. Not only does the technique show promise in pollution abatement but the design of the cryogenic device permits it to be used as a monitor. As an integrating pollution meter it appears to be three orders of magnitude more sensitive than any existing commercial monitor. So far tests have shown cryogenic trapping is capable of removing sulfur dioxide, hydrogen sulfide, and methyl mercaptan. The technique is potentially capable of removing from air streams any condensable hydrocarbon. In addition to developing the cryogenic trapping device as a pollution monitor, the possibility of applying cryogenic techniques to internal combustion engine

emissions, radioactive gases from nuclear reactors, and SO2 pollutants from coal burning furnaces will be investigated.

SUPPORTED BY U.S. National Science Foundation

1.0625, REGENERATION OF CARBON ADSORBENTS FOR SO2
R.W. COUGHLIN, Lehigh University, School of Engineering, *Bethlehem, Pennsylvania* 18015

Work will be continued in testing and evaluating schemes and processes for regenerating active carbon loaded with SO2 and sulfuric acid. Various techniques using water, bases and reducing agents will be studied. In addition, work will continue in developing a mathematical model to describe the simultaneous sorption, chemical reaction and regeneration that occurs during countercurrent flow of SO2 bearing gases and aqueous solution through a sorbent bed of carbon.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0626, IMPROVEMENT OF URBAN TRANSPORTATION
UNKNOWN, Day & Zimmerman Incorporated, *Philadelphia, Pennsylvania*

A utilization study is being conducted of methods to obtain improved results from existing transportation technologies. Improvements to ameliorate air pollution, traffic congestion, transit failings, and citizens total lack of access to economical and convenient transportation are being analyzed for introduction into cities and towns.

Document provided by Highway Research Information Service.

SUPPORTED BY U.S. Dept. of Housing & Urban Development

1.0627, THE DUST LAYER AND PRECIPITATOR EFFICIENCY
G.W. PENNEY, Carnegie Mellon University, School of Engineering, *Pittsburgh, Pennsylvania* 15213

The study relates to precipitator troubles which are associated with the layer of collected dust. It is primarily directed to two very different, but interrelated properties, adhesion of the dust, and sparkover originating in the dust layer.

The mechanism of adhesion is being studied to obtain information regarding the best means for removing the dust. Empirical methods for evaluating adhesion properties are being developed.

Tests are being made with perfectly adhering particles and compared with results using more typical dusts in order to evaluate losses due to imperfect adhesion.

In the study of sparkover, the mechanism by which the sparkover develops, and the influence of various precipitator conditions are being investigated. The relationship between sparkover voltage and circuit capacitance is being studied in order to improve the prediction of the performance of a full size precipitator from tests on a small unit.

The effects of various gases on the development of a spark are being investigated in order to predict effects of gas composition on precipitator operation.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0628, SO2 SORPTION BY AND REMOVAL FROM POLYMERIC MATERIALS
R.L. ZAHRADNIK, Carnegie Mellon University, School of Engineering, *Pittsburgh, Pennsylvania* 15213

The overall objective of this project continues to be the investigation of macroreticular ion exchange resins as SO2 sorbent materials. Research during the current year has focused on the determination of the sulfur dioxide (SO2) sorption rate and capacity of a number of specific resins.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0629, REMOVAL OF SULFUR OXIDES FROM FLUE GAS
M. BERMAN, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

Selected sorbents will be studied as follows: Utilizing high angle X-ray diffraction, determine phases present in sorbents showing good activity but limited attrition resistance or those having limited activity but good resistance at stages in the preparation, sorption, and regeneration cycle.

Analyze line profiles and line broadening of the active phases to determine crystallite forms and sizes and possible phase shifts during the cycle.

Study small-angle X-ray patterns of the above sorbents to determine pore sizes and shapes as they affect sorptive capacity and sorption rates.

Investigate possible function of iron in promoting reduction of the spent sorbents. Utilize X-ray fluorescence, electron microscopy, and electron diffraction to aid in this study.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0630, ENVIRONMENTAL CONTROL RESEARCH - CONTROL TECHNIQUES DEVELOPMENT
J. CERVIK, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

The flow of gas through coalbeds is controlled by definite laws and, therefore, methods of controlling gas flow during mining naturally follows from these laws. However, before meaningful measurements can be made underground of control methods developed, equipment and apparatus to accomplish this task must be developed. Measurement of the virgin gas pressure of coalbeds requires the drilling of smooth walled, horizontal holes, 400 feet or more in length, incrementally and suitably packing the hole to measure gas pressure. Packers to accomplish this task are not suitable and are too costly. Therefore, a relatively inexpensive and reliable packer is being developed in cooperation with the rubber industry. These packers also will be used in underground experiments to determine the effects of waterflooding, and the use of unstable foams as a means of diverting the flow of gas from active face areas. The use of surface boreholes to degasify coalbeds in advance of mining is also being investigated.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0631, CHARACTERISTICS AND REMOVAL OF PYRITE FROM AMERICAN COALS
A.W. DEURBROUCK, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

The objective is to determine the degree of correlation between the removal of pyritic sulfur by conventional washing methods and the size and mode of distribution of the pyrites. Coal samples sized 1- 1/2 inch by 100 mesh, 3/8 inch by 100 mesh, and 14 mesh by 0 will be washed at specific gravities of 1.30, 1.40, and 1.60.

Atmospheric pollution by sulfur oxides originates mainly from the combustion of fossil fuels to generate heat and power. Pyritic sulfur, depending on the manner in which it is distributed in coal, can be removed substantially by conventional gravity-separation methods used in coal preparation processes.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0632, POTENTIAL SORBENTS AND CATALYSTS FOR SO2 REMOVAL FROM FLUE GASES
J.H. FIELD, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

Purpose: To develop new processes for removing sulfur oxides from flue gas by assaying materials as to their absorptive capability and subsequent regeneration characteristics. The development of a cyclic process with a salable by-product is the objective, but alternative systems using very cheap disposable absorbents will also be studied.

PART A: Emphasis will be given to investigating inexpensive minerals, ores, or waste products. Two bench-scale units, each comprising an absorber and regeneration system will be constructed. A simulated flue gas will be used. Types of material to be tested include clays, bauxites, oil shales and oil-bearing sandstones, phosphate rocks, and mineral ores.

PART B: Gaseous SO2 will be reacted with metal carbonyls (cobalt, manganese, iron) and metal complexes and the ease of formation of insertion compounds will be studied.

PART C: Spent absorbents from the most promising materials from Part A and Part B will be studied by the spectrometric group to identify products formed, and provide information to optimize development of new SO2 removal processes.

PART D: Materials from Part A which are active absorbents will be tested with gas from combustion of pulverized coal. This will require construction of a furnace burning 20-25 lbs coal/hr.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0633, REMOVAL OF SULFUR OXIDES FROM FLUE GAS

W.P. HAYNES, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

Assay of Potential Sorbents and Catalysts. Continue bench-scale assay of new materials, particularly those of low cost. Tests will be made with simulated flue gas containing 0.3 percent SO2, 0.05 percent NOx, 4 percent 02, 12 percent CO2, 6 percent H20, and the balance nitrogen. SO2 removal efficiency will be studied for these selected materials at temperatures in the range of 130 degrees to 600 degrees C and an hourly space velocity around 1050. Materials active as sorbents will be tested for thermal regeneration and by regeneration via reduction.

Sorbent Testing. Intensive tests will be made of tentative sorbents which appear to show merit for further study as a result of basic studies conducted by the spectroscopic and solid state physics groups.

Chemical stability will be studied in actual flue gasses by conducting cyclic adsorption-regeneration tests using flue gas from onsite combustion of sulfur-bearing fuel in a laboratory furnace.

In addition and if time permits, it may be desirable to design, construct, and test a bench-scale tray-type absorber in which the flue gas contacts the surface of thin layers of sorbent. The would permit the evaluation of the performance of the absorbents in a reactor that could have a low attrition loss, low pressure drop, and yet might provide ample gas-solids contact surface.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0634, VORTEX INCINERATION OF COMBUSTIBLE WASTES

C.H. SCHWARTZ, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

To conduct research on incineration. A pilot-scale vortex incinerator with a nominal capacity of 200 pounds of refuse per hour has been designed, constructed and tested. It is refractory-lined, provided with continuous charging, agitation, and has ports for directing secondary air to the center of the vortex.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0635, POTENTIAL SORBENTS AND CATALYSTS FOR SO2 REMOVAL FROM FLUE GAS--PART C

A.G. SHARKEY, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

Spectrometric Analyses of Sorbents and Sorbates - Selected sorbents will be analyzed by infrared and spectrometric methods to identify the formation of new compounds; and spectra of products from spent sorbents as well as time-temperature patterns of products from regeneration will be studied.

The effect of nitrogen oxides on the sorption of SO2 and regeneration of sorbents will be studied.

Combined differential thermal analysis-mass spectra techniques will be used to study reactions of sorbents with SO2 at selected temperatures. Temperature of reaction, weight change, and specific gases associated with the reaction will be determined simultaneously.

High-resolution mass spectrometry (direct probe technique) will be applied to study in detail all gases obtained from spent sorbents.

Survey runs of original, spent, and regenerated sorbents for SO2 will be made by electron spin resonance to search for paramagnetic species and the effect of SO2 on such species.

Low-power laser irradiation of surfaces of sorbents will be carried out to determine the concentrations of sorbed gases at the surface and to study the relative bond strengths between sorbates and catalyst.

The sorption and regeneration of sorbents will be monitored by a system constructed around a high-sensitivity mass spectrometer, to determine accurately and continuously the chemistry and physics of sorbent systems.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0636, INCLUSION ADDUCTS FOR AIR PURIFICATION

H.R. ALLCOCK, Penn. State University, School of Science, *University Park, Pennsylvania* 16802

The principal objective of this work is the synthesis and evaluation of a new series of clathrating compounds based on the cyclophosphazene system. It has recently been shown that several crystalline compounds of structure, (NPR2)3, form strong inclusion adducts with organic vapors. These materials appear to be particularly promising candidates for the removal of air pollutants from the atmosphere either in air purification equipment or in pollution testing equipment.

This project is designed to evaluate as many candidate compounds as possible, to examine the adducts by X-ray diffraction, and to determine which compounds are most suitable for this application.

Research on this project does not include human subjects.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0637, SORPTION OF GASEOUS POLLUTANTS BY CYCLED OPERATION

A.J. ENGEL, Penn. State University, School of Engineering, *University Park, Pennsylvania* 16802

The combined process of absorption and adsorption of a gaseous pollutant in a slurry of a solvent and an adsorbing agent has been entitled 'sorption'. Previous studies have shown it to hold a great deal of promise for the effective removal of pollutants from gaseous emission streams. At the same time, the cyclic operation of absorption equipment has proven to be very efficient, and it appears reasonable, therefore, to attempt to merge these two techniques for (1) studying the fundamental parameters governing the sorption process and (2) determining the feasibility of operating a cycled sorption column successfully.

The proposed research will deal with the continuous sorption of sulfur dioxide in an air stream into a sorption suspension of activated carbon in water. It will be carried out in a cyclically operated sieve- place column. Ultimately, this work will be extended to simulated coal- furnace flue gases and the removal of other pollutant gases from a variety of exhaust streams.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0638, USE OF ELECTRIC FIELDS IN COMBUSTION

R.J. HEINSOHN, Penn. State University, Center for Air Env. Studies, *University Park, Pennsylvania* 16802

Electric fields have a pronounced effect on the geometry, flammability limits, heat transfer, luminosity and carbon formation of flames. While research in this country and Europe concerning this flame-field interaction is currently in progress, sufficient evidence exists to suggest that electric fields may be used to suppress pollutant production.

Electric fields may suppress pollutant production in either (or both) of two ways. The flame-field interaction might result in a direct alteration of combustion chemistry and consequently pollutant production. In addition, the interaction might result in indirect suppression by enabling the combustor to satisfactorily burn fuel oxidant mixtures in proportions which of themselves produce tolerably small pollutant amounts. It is proposed that a study of the production of carbon and nitrogen oxides in flames subjected to electrostatic fields be conducted.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0639, ENTHALPIMETRIC ANALYSIS
J. JORDAN, Penn. State University, Graduate School, *University Park, Pennsylvania* 16802

The thermodynamics of interesting acid-base, complexation and oxidation-reduction processes will be explored. Organic functional group reactions will be investigated with a view to obtaining information on thermochemical substituent effects, bond strengths and mechanisms. It is anticipated that methods developed may revolutionize organic functional group analysis. The thermochemistry of immunological reactions will be studied systematically. Concomitantly, instrumental methods of antibody-antigen analysis will be developed. Other significant areas include: accurate measurement of heats of reaction between gases and liquids and applications to gas analysis and atmospheric pollution control; endothermic-exothermic reaction sequences due to entropy effects; and micro-scale miniaturization of enthalpimetric analysis.

This research represents a continuation of that currently being supported by Foundation grant GP-11386.

SUPPORTED BY U.S. National Science Foundation

1.0640, ENGINE EMISSION REDUCTION BY COMBUSTION CONTROL
W.E. MEYER, Penn. State University, School of Engineering, *University Park, Pennsylvania* 16802

The proposed work is to supplement the research under the original grant with respect to emissions in the range of engine operating conditions which extend from normal into the knocking regime. It is particularly intended to find out if the emission picture can be generalized over a broad range of the knock intensity scale developed under the original grant. Further investigations concerning irregularity of emissions from cycle to cycle are to be carried out. Bomb experiments are proposed which are novel in that they combine sampling of gases with a microprobe near the bomb wall and observation of the sampled region with an interferometer. Through these several techniques it is hoped to show new ways to emission control and better describe the engine combustion process in terms of the conditions and processes which produce undesirable combustion products.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0641, THE BINDING AND ACTIVATION OF SMALL COVALENT MOLECULES BY TRANSITION METAL COMPLEXES
J.A. STANKO, Penn. State University, School of Science, *University Park, Pennsylvania* 16802

The research will involve chemical studies of the binding and activation of the gaseous non-metal oxides, carbon monoxide, sulfur dioxide, nitric oxide and nitrogen dioxide by transition metal complexes. The work will include both x-ray crystallographic and electronic structural studies of the complexes under investigation. The planned studies have relevance to the field of air pollution control in that they have the potential for affording new chemical means of control of such oxides in an air environment through the ability of the metal complexes to promote the chemical reactions necessary for the conversion of these oxides to less noxious substances.

SUPPORTED BY U.S. National Science Foundation

1.0642, INTERACTION OF FLUE GASES WITH CARBON SURFACES
P.L. WALKER, Penn. State University, School of Earth Sciences, *University Park, Pennsylvania* 16802

The work proposed is closely linked to the over-all objective of removal of SO2 from flue gases using carbon. We have shown that it is technically feasible to remove SO2 from flue gases at 800 degrees C by interaction with carbonaceous solids. In the process, COS and H2S are produced, as well as an activated carbon. We now propose to examine the fundamentals and kinetics of air oxidation of COS and H2S to elemental sulfur over microporous carbon surfaces at temperatures between 130-200 degrees C. The importance of metallic and oxide impurities in catalyzing the reaction will be studied by comparing the activity of commercially available active carbons (of reasonably high impurity contents) with a high purity carbon especially prepared by the activation of carbonized Saran.

1.0643, DEVELOPMENT OF NAVY METAL SURFACE TREATMENT PROCESSES FOR COMPLIANCE WITH POLLUTION CONTROL REGULATIONS
S.R. BROWN, U.S. Navy, Air Development Center, *Warminster, Pennsylvania* 18974

Technical Objective: Develop and evaluate metal surface treatment processes and materials in conformance with pollution regulations for application at Naval rework facilities.

SUPPORTED BY U.S. Dept. of Defense - Navy

1.0644, INVESTIGATION AND ANALYSIS OF GASES AND CRYOGENIC MATERIALS USED IN NAVAL AIRCRAFT
E.R. WRIGHT, U.S. Navy, Air Development Center, *Warminster, Pennsylvania* 18974

Technical Objective: To develop methods for the qualitative and quantitative analysis of gases and cryogenic materials, and contaminants contained therein, for which analyses have not been established. The ultimate objective is to provide gaseous systems with materials that will produce environmental operating conditions for the pilots and crew for safe and effective operation of the aircraft.

SUPPORTED BY U.S. Dept. of Defense - Navy

1.0645, REGENERABLE CHAR SORPTION PROCESS FOR SOX CONTROL
UNKNOWN, Westvaco Corporation, *Charleston, South Carolina*

Description: This effort represents a step in process development on the pilot plant scale using sorbent/regenerator capacity equivalent to some 600 cph of flue gas. Up to this stage, the process was researched and advanced privately by Westvaco. The major goal of this effort is to determine whether or not the proposed process chemistry can be effected and controlled on a continuous basis in the integrated pilot plant. Also engineering design of a 20,000 cph plant will be produced under this contract.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0646, SEPARATION AND COLLECTION OF COTTON GIN DUST
W.E. GARNER, U.S. Dept. of Agriculture, S.E. Cotton Ginning Res. Lab., *Clemson, South Carolina* 29631 (308-037-C109)

OBJECTIVE: Develop low-cost methods for unloading and conveying seed cotton and its components, and collecting and disposing of materials incident to ginning.

APPROACH: Conduct basic studies, primarily electrostatic principles, of dust and trash collection for an airstream and develop and evaluate air-wash systems suitable for gins as an alternative method for separating foreign matter from the air. Construct and test these devices on a pilot basis and analyze the type and amount of foreign matter entering and leaving the system as a means of determining their acceptability by the industry. If promising, conduct tests under commercial conditions before making final recommendations.

PROGRESS: An experimental inertial separation chamber effectively collected particulate matter discharged from the seed cotton unloading system. Injecting water spray into the chamber reduced emission to the atmosphere up to 92 percent, compared with dry operation. Plans for design and operation of the chamber were prepared. A commercial centrifugal separator effectively provided suction for unloading seed cotton from trailers, and also collected a high percentage of particulate matter from the discharged air. Discharging air from the centrifugal separator into the inertial separation chamber during wet operation controlled emission of small particles. The centrifugal separator is not suita-

ble for handling air containing fibrous material. At selected commercial gins approximately 65 percent of total connected horsepower was applicable to materials handling and collecting systems. Power consumption varied from 28 to 71 kw.-hr/bale. Tests showed that significant savings in power costs can be made by more efficient gin plant operation. In tests to determine the electrostatic force on cotton, attractive force of the positive charged plate of a capacitor was 11 to 17 dynes while the repulsive force was 1 to 3 dynes at 50 percent relative humidity and a field strength of 895 to 1075 volts/cm. This method was approximate, since drag forces was neglected.

1.0647, PILOT PLANT STUDY OF AMMONIA SCRUBBING OF POWER PLANT STACK GASES
T.M. KELSO, U.S. Tennessee Valley Auth., *Knoxville, Tennessee* 37902

Description: A slip stream (3000 SCFM) of flue gas from a coal- fired power plant will be treated in a number of different scrubber designs. Aqueous solutions of ammonia will be used as the scrubbing medium. An experimental program will be designed to determine SO2 and particulate removal efficiencies as functions of scrubber design and operating parameters. Performance data will be used to evaluate whether NAPCA should pursue development of a closed-100p, regenerable ammonia process for SO2 recovery.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0648, CONSTRUCTION AND OPERATION OF LIMESTONE-WET SCRUBBING TEST FACILITY
A.V. SLACK, U.S. Tennessee Valley Auth., *Knoxville, Tennessee* 37902

Objective: Reach the 90% completion stage in construction of test facility.

Description: TVA will construct NAPCA's limestone-wet scrubbing test facility at Shawnee Power Station according to Bechtel-furnished design and engineering and using major equipment procured by Bechtel. TVA will furnish bulk construction materials and certain specific items not supplied by Bechtel. Following construction, TVA will provide operating manpower for start-up and operation of the unit during the test program. In addition TVA will participate on the technical teams on directing the work during the test program phase.

1.0649, DESIGN STUDY FOR AIR FORCE ROCKET PROPULSION LAB EXHAUST GAS CLEANING SYSTEM
J. GARRETT, Aro Incorporated, *Tullahoma, Tennessee* 37389 (F40600-71-C-0002)

Technical Objective: This effort is a study to determine the most technically and economically feasible exhaust detoxification system for rocket test stands at the AFRPL and a design of a pilot system to demonstrate the performance of the system. Phase 1 will consist of investigating methods of scrubbing the exhaust gases of rockets up to 250,000 lbs thrust. Phase 2 will result in the design of a prototype scrubber system for a 5000 lb thrust rocket test stand at AFRPL.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0650, SAMPLING AND ANALYTICAL METHODS DEVELOPMENT FOR PROTOTYPE LIMESTONE - WET SCRUBBING TESTS
P.S. LOWELL, Radian Corporation, *Austin, Texas* 78758

Objective: Develop accurate and reliable sampling and analytical methods for laboratory and field use during pilot plant and prototype tests of limestone-wet scrubbing processes.

Description: Efficient conduct of the wet scrubber test program at the Shawnee test facility and planned pilot plant projects in support of this program will require adequate methods for sampling and chemical analyses of major liquid process streams. The purpose of the present study will be to evaluate, select, and adapt methods and equipment for rapid and accurate determination of the important chemical species in limestone-wet scrubber processes. The methods and equipment recommended will be based on accuracy in the presence of interfering compounds, on the need for rapid analysis, and on simplicity and reliability. The study will also include development of techniques for handling and treating samples to prevent composition changes between time of sampling and analysis.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0651, RI - ADAPTIVE MIXTURE CONTROL FOR INTERNAL COMBUSTION
J.J. ALLAN, Univ. of Texas, School of Engineering, *Austin, Texas* 78712

Recent efforts to reduce exhaust emissions have been directed at improved combustion chamber design and more accurate fuel/air mixture control. The purpose of this work is to investigate the feasibility of taking the next logical step beyond basic feedback fuel/air mixture control systems.

Introducing adaptive control techniques into an electronic fuel injection system allows the modification of the fuel/air ratio algorithm based upon actual analysis of the exhaust gas constituents. Such a system would continuously monitor and modify performance index using analog computation. The work under this proposal would use a digital computer to begin an investigation of an adaptive algorithm that would allow such considerations as 'cold' starts and acceleration. Decreased levels of undersirable engine emissions are to be obtained while retaining engine performance.

SUPPORTED BY U.S. National Science Foundation

1.0652, AIR POLLUTION CONTROL FLUIDIZED VORTEX INCINERATION
J.P. HOLMAN, Southern Methodist University, School of Technology, *Dallas, Texas* 75222

The second year of this project will collect specific data pertaining to fluidization and swirl characteristics of a vertical vortex incinerator. Ash collection characteristics will be measured as well as localized heat transfer along the vertical length of the furnance. Shredded paper will be used for burning with propane augmentation at the inlet to the incineration. The influence of various tangential flow rates on the above parameters will be studied.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P H.S.

1.0653, COTTON MATERIALS HANDLING, COLLECTION, AND DISPOSAL IN THE TEXAS STRIPPER COTTON AREA
R.V. BAKER, U.S. Dept. of Agriculture, S. Plns. Cotton Gin. Res. Lab., *Lubbock, Texas* 79401 (308-035-C112)

OBJECTIVE: Develop low-cost methods for unloading and conveying seed cotton and its components, and collecting, packaging, and disposing of materials incident to ginning.

APPROACH: Investigate commercially available filter systems for possible adaptation for handling the heavy loads imposed by cleaning machine-stripped cotton. Study, adapt, and/or develop new principle of air-particulate matter separation to the ginning operation. Develop methods of handling and conveying with less power materials incident to ginning.

PROGRESS: The operating capacity of an air-belt lint feeder for a gin press was found to be 11 pounds of lint per tramper stroke. A round air filter for condenser exhausts was constructed and tested. This unit performed the same function as a standard inline air filter but was less costly to build and install. Dust losses from two types of inline air filters and a covered condenser drum were determined for several condenser locations. A pilot model seed cotton feeder for baled seed cotton was tested and found to be feasible for handling compacted masses of seed cotton.

1.0655, NON-FERROUS SMELTER CONTROL TECHNOLOGY
UNKNOWN, Battelle Memorial Institute, *Richland, Washington* 99352

Projected study will probe the feasibility of partially oxidizing MeS, specifically, Cu ore stream for H2S production which then could be reacted with SO2 in other smelter streams for production of elemental sulfur and thus preventing emission of sulfurous gases into the atmosphere.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0656, ENGINEERING SYSTEMS FOR UTILIZATION OF HEAVY TIMBER STANDS OF THE PACIFIC COAST INCLUDING ALASKA
H.H. LYSONS, U.S. Dept. of Agriculture, Pac. Nw. For. & Rg. Expt. Sta., *Seattle, Washington* (PNW3701)

OBJECTIVE: Improve the efficiency and mechanization of materials handling and transportation systems for forestry operations in heavy timber on difficult access areas with emphasis on harvesting by aerial methods while safeguarding watershed, soil aesthetic and recreation values.

APPROACH: Develop design and performance criteria and parameters through systems analysis for logging systems for difficult access areas including Alaska. Emphasis to be given to balloon, skyline, and helicopter methods; and methods of removing and utilizing logging residues to reduce air pollution from any slash burning. Engineering systems analysis techniques will be used in the development of improved materials handling systems.

PROGRESS: A two-line mechanically-operated slack-pulling carriage has been designed for use with running skyline systems. Development of this carriage and yarding system will make it economically feasible to greatly extend yarding distances and harvest partial cuts in areas previously considered not commercially accessible. A USDA patent application is being prepared to cover this invention. A means has been developed to employ desk-top programmable calculators and plotters for skyline designs. This will provide almost instant design results where previously there was either a delay time of one to four weeks on the large central computers, or costly man-hours were consumed on tedious manual procedures.

SUPPORTED BY U.S. Dept. of Agriculture

1.0657, ODOR FORMATION IN ALKALINE PULPING
K.V. SARKANEN, Univ. of Washington, School of Engineering, *Seattle, Washington* 98105

The broad objectives of this program are to develop means of reduction or elimination of odor release from alkaline pulping processes, through a team effort in the following areas. 1. To evolve fundamental information on the formation of malodorous methyl mercaptan and dimethyl sulfide in the kraft batch and continuous pulping processes, and on the factors governing the atmospheric release of these two components together with possible other sulfur compounds during the various phases of the process. 2. To develop alternative process modifications for kraft pulping through engineering design studies, so as to avoid or minimize release of odorous compounds. 3. To explore new ways to delignify wood under alkaline conditions in order to determine whether or not an intrinsically odor-free alkaline pulping process is feasible.

1.0658, REMOVAL OF PYRITE FROM COAL BY DRY METHODS
W.T. ABEL, U.S. Dept. of the Interior, Bureau of Mines, *Morgantown, West Virginia*

Purpose: Since pyrite contributes substantially to the sulfur content of utility coals its removal prior to burning reduces sulfur dioxide in stack gases. This program involves the selective dry grinding (ball mill and race mill) of coal-pyrite blends and coals to liberate the pyrite from the coal for subsequent removal by air classification and electrostatic separation. Work has been directed toward optimizing grinding times, presizing of the ground coal for most effective centrifugal separation and investigating variables in the electrostatic process.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0659, REMOVAL OF PYRITE FROM COAL BY DRY METHODS
W.T. ABEL, U.S. Dept. of the Interior, Bureau of Mines, *Morgantown, West Virginia*

Purpose: Since pyrite contributes substantially to the sulfur content of utility coals its removal prior to burning reduces sulfur dioxide in stack gases. This program involves the selective grinding (ball mill race mill) of coal-pyrite blends and coals to liberate the pytire from the coal for subsequent removal by air classification and electrostatic separation. 1.0660, FLUIDIZED-BED COMBUSTION
N.H. COATES, U.S. Dept. of the Interior, Bureau of Mines, *Morgantown, West Virginia*

Purpose: To investigate fluidized-bed combustion as a boiler firing technique which may offer methods for reducing the emission of pollutants from coal-fired boilers. Goals for fiscal year 1970 include investigations of 1) amenability of various coals for combustion in a fluid-bed boiler, 2) erosion, corrosion and deposition associated with heat transfer surfaces in a fluid bed, and 3) heat-transfer characteristics of a fluid-bed boiler.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0661, REDUCED SO2 IN COMBUSTION GASES
C.C. SHALE, U.S. Dept. of the Interior, Bureau of Mines, *Morgantown, West Virginia*

Purpose: Conduct exploratory studies on processes for removing sulfur oxides from stack gases.

Pilot-Scale Study for Removal of SO2 from Stack Gases with Ammonia - Sulfur dioxide from the combustion of coal is a contributor to air pollution and presently is the primary target in abating air pollution from stationary power generators. Previous laboratory-scale efforts to remove SO2 from simulated stack gas by vapor-phase reactions with ammonia have been successful. Results of this work show that complete removal of SO2 from the gas phase is obtained with conversion to a solid salt using a residence time under one- half second in the vapor-phase reactor. Subsequent removal of the solid salts from the gas is obtained by water scrubbing.

After establishing operability of the process in a continuous system, data on operating characteristics will provide a broader and more significant base for determining operating costs.

SO2 Removal Using Pyrite Sorbent - Evaluate on a small scale the removal of sulfur dioxide from stack gas by reaction with metal sulfides. An immediate objective is to achieve the simultaneous conversion of sulfur dioxide to elemental sulfur and of pyrrhotite to iron oxide.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0662, STACK GAS SULFUR REMOVAL PROCESSES
C.C. SHALE, U.S. Dept. of the Interior, Bureau of Mines, *Morgantown, West Virginia* 26504

Purpose: To explore (a) vapor-phase reactions of ammonia, water, and the acidic components in simulated powerplant stack gases; (b) removal of the resulting finely divided solid ammonium saltes in a water scrubber; and (c) regeneration of ammonia from the recovered salts.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0663, WET SCRUBBER STUDY - VENTURI SCRUBBER AND TURBULENT BED CONTACTOR
C.Y. WEN, West Va. University, Graduate School, *Morgantown, West Virginia* 26506

Description: Mathematical models describing the process characteristics will be developed for the venturi scrubber and turbulent bed contractor in controlling sulfur dioxide and particulate emissions. Computer simulations of process variables under a variety of operating conditions will be performed. Optimization studies will be undertaken on both performance and economic factors. Sensitivity analysis will be performed on the optimum solutions. Recommended design parameters for these units will be identified. Information generated will be an input to the prototype limestone-wet scrubbing plant to be built at the TVA facility.

1.0666, LIDAR PROBING OF THE ATMOSPHERE
J.A. REAGAN, Univ. of Arizona, School of Engineering, *Tucson, Arizona* 85721

The purpose of this research is to conduct a program on the development and application of lidar as a remote atmospheric probe. The program will be carried out jointly by the Electrical Engineering Department and the Institute of Atmospheric Physics.

The experimental phase of the research will be concerned primarily with utilizing the bistatic lidar system now being constructed to obtain measurements of the intensity and polarization of angularly scattered laser light as a function of height under various meteorological conditions. Data from these measurements will be used to infer information about the sizes and concentrations of atmospheric aerosols and to determine the sensitivity of lidar to various structural features in the atmosphere.

Results from concurrent theoretical studies will be used to aid in interpreting the lidar measurements, particularly with regard to inverting to inverting lidar measurements to determine the aerosol distribution function.

The research is unique in that it will permit measurements of both intensity and polarization (the four Stokes parameters) of the angularly scattered light. This capability will provide considerably more information concerning the distribution of absorbing and scattering constituents in the atmosphere. Theoretical work indicates that this is the case.

SUPPORTED BY U.S. National Science Foundation

1.0667, NAVY ENVIRONMENT - COMPUTER CONTROL OF CHEMICAL INSTRUMENTS
G.S. WILSON, Univ. of Arizona, School of Liberal Arts, *Tucson, Arizona* 85721 (N00014-67-A-0209-0014)

Technical Objective: The Navy uses instruments such as gas chromatographs for identifying and measuring trace toxic materials in the atmospheres of closed environments, for example in submarines. It is the purpose of this research to improve the performance of such instruments by computer-aided optimization of the conditions under which the instrument operates.

SUPPORTED BY U.S. Dept. of Defense - Navy

1.0668, HIGH ALTITUDE BALLOON SAMPLING PROGRAM (PROJECT HIBAL)
J.W. HILLIER, Australian Dept. of Supply, *Mildura, Victoria, Australia* (AT(49-7)1908)

Project 'HIBAL' is a cooperative U.S. Australian effort to provide stratospheric air samples from the Southern Hemisphere. High volume balloon-borne air filter samplers are flown quarterly at altitudes of 70,000, 80,000, 90,000, and 105,000 at Mildura, Victoria, and semi- annually at Longreach, Queensland, Australia. Occasional samples are obtained at Mildura from 120,000 and 135,000 feet. Samples are forwarded to the AEC Health and Safety Laboratory in New York. Radiochemical analysis is carried out by HASL on contractor analytical laboratories under HASL management. Several fission products are analyzed routinely and at times shorter-lived and selected trace elements the Air Resources Laboratory, Environmental Science Services Administration for evaluation and interpretation as related to fallout mechanisms and to the inventory of fallout radioactivity in the stratosphere.

SUPPORTED BY U.S. Atomic Energy Commission

1.0669, STUDIES ON AEROSOLS OF SIZES DOWN TO 0.05 MICRON
O. PREINING, Univ. Wien, *Vienna, Austria*

The work mainly covers methods of aerosol sizing down to small particles: I) Aerosol spectrometers: The selectivity (resolution power) of the instruments could be increased under special operating conditions to 1:10 to minus the 3rd power. For spray-dried Dow latex Aerosols of .79 u. The selectivity was measured to 5,5.10 to minus the 3rd power.

II) Condensation nuclei counter: Investigations with the previous reported model showed that the growth rate of droplets at the beginning of growth depends on the hygroscopicity of the nuclei. To investigate further into this interesting phenomenon the automatic instrument will be completely rebuilt to permit measurements in the .1 ms time range in dependence on the expansion ratio. A new light source (laser) and a modulator with a short time constant for it will be used.

III) Photochemical aerosol production: Decomposition of H2S in N2 by UV-irradiation produces particles. Suitable conditions permit to produce S-Aerosols of a standard deviation of their Stokes-diameters of c.1o % with mean particle sizes of about 1 micron diameter.

IV) Detection of Submicron particles: An experimental cooling stage for a microscope was designed, which permits exposure

of samples of aerosol deposites to differently humidified atmospheres. First experiments with NaCl particles on varnished paper foils yielded the following: NaCl particles of .7 micron geometric diameters start to grow at a temperature of plus 16 degrees C foil temperature; such of .14 micron at 11.8 degrees C if the atmosphere (N) is saturated at 18 degrees C. A clean foil condenses particles on it at plus 7 degrees C.

1.0670, DEVELOPMENT OF AN IMPROVED NON-DISPERSIVE INFRARED ANALYZER FOR CARBON MONOXIDE
W. LINK, Arkon Scientific Laboratories, *Berkeley, California* 94710

The work proposed in this task element is intended to provide NAPCA with an improved NDIR CO analyzer based on fluorescent emission of carbon monoxide. This technique could serve as forerunner of a family of inexpensive instruments capable of measuring both source and ambient levels of a variety of pollutants.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0671, DEFINE AND DEVELOP UNIFORM PROCEDURES FOR MEASURING PERFORMANCE EVALUATION PROCEDURES FOR CONTINUOUS ATMOSPHERIC ANALYZERS
T.W. STANLEY, State Dept. of Pub. Health, *Berkeley, California* 94704

Define performance criteria and develop uniform and acceptable procedures for measuring these criteria. Criteria to be investigated, where practical, will include but not be limited to the following: Analyzer, pollutants measured, detector, absorber, range(s), reagents, power requirements, physical dimensions, flow diagram, reagent utilization, and an overall appraisal. The above criteria will have subcategories such as zero drift, span drift, electronic drift, reliability, readability, sensitivity, integration of output signal, lag time, response time, collection efficiency, effect of flow rate, and interference equivalents.

Representative types of continuous air analyzers for pollutants such as sulfur oxides, carbon monoxide, oxides of nitrogen, ozone and oxidants will be evaluated.

The criteria selected and procedures developed shall be consistent with a subsequent goal of defining the minimum performance specifications of analyzers. Guidelines will be established by recommendations of the SAD and the Intersociety Committee. Priorities will be established by the NAPCA and the present or anticipated issuance of Air Quality Criteria Documents and the publication of Standards in the Federal Register.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0672, A NEW INSTRUMENT FOR KINETIC STUDIES OF AIR POLLUTION
K.D. BAYES, Univ. of California, School of Letters, *Los Angeles, California* 90024

The proposed research will attempt to develop a photoionization mass spectrometer which could be applied to a wide variety of air pollution problems. The instrument should have a senstivity in the ppb range with a high selectivity for most pollutants. It is planned to use the instrument to measure the rate constants for certain reactions involving reactive intermediates, such as free radicals, NO3, O2. The instrument should also be useful for monitoring pollutants in the atmosphere, although that is not part of the proposed study.

The aim of this study would be to provide critical rate constants which are needed in computer simulation studies. Certain neglected reactions would also be studied. The more reactions and rate constants that are known experimentally, the greater the probability that such simulation studies will reflect the actual environment. Computer studies are needed to establish priorities on pollutant controls.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0673, MOLECULAR-BEAM SAMPLING FROM CYCLING-PRESSURE SOURCES
E.L. KNUTH, Univ. of California, School of Engineering, *Los Angeles, California* 90024

The objective of the proposed project is to investigate the feasibility of using molecular-beam techniques and a mass spectrometer in studies of sampling from combustion chambers of reciprocating internal-combustion engines. If such sampling studies were feasible, they would facilitate direct measurements of the composition and temperature of the gas mixture in the combustion chamber. Such information would be valuable in efforts to identify the important reaction mechanisms and in subsequent efforts to control the composition of the gases exhausted by automobile engines.

The relatively complicated problem of direct sampling from automobile engines is being approached via a series of increasing complex studies on a small motored engine. Measurements have been made on a pure gas and on three inert binary mixtures. It is proposed to make measurements now on a dissociating-recombining binary gas mixture and then on a more complicated reacting gas mixture. If feasibility of the method is demonstrated in these preliminary studies, then a proposal for sampling from combustion chambers of automobile engines would be prepared.

1.0674, LIDAR MEASUREMENT OF BACKSCATTER COEFFICIENT RELATED TO INFRARED EMISSIVITY OF CLOUDS
P.A. DAVIS, Stanford Research Institute, *Menlo Park, California* 94025 (003200)

Approach: The LIDAR will be mounted on an aircraft and flown over the BOMEX area during July 1969. The transmitter receiver will be a co- aligned telescope and will be fired when the range is clear and when ideal conditions exist. Information about the physical dimensions of the cirrus clouds, the relative backscatter from clouds, lidar returns from haze layer and the extent of the haze layer will be documented. Concurrent radiometric measurements will be taken and finally the lidar and IR measurements will be integrated to study the properties of the cirrus clouds. As a further comparison between experimentally measured values, particle count and size date obtained by Colorado State University on the same flights will be used to compute expected values and compared with actual measurements.

Measurements of laser backscattering from clouds were made with an infrared radiometer in the 10-12-micron band during BOMEX and during local flights from Moffett Field, California. A final report is in preparation comparing the infrared transmittace and emittance from the two devices.

SUPPORTED BY U.S. Dept. of Commerce - E.S.S.A.

1.0675, CARBON MONOXIDE DIFFUSION MODEL
W.B. JOHNSON, Stanford Research Institute, *Menlo Park, California* 94025

Conduct field tests in San Jose, California and another city (to be selected) to measure CO concentrations and meteorology, for validating a diffusion model for predicting automotive generated pollutant (CO) concentration distribution in any urban area.

Contract sponsored jointly with Coordinating Research Council (CRC).

1.0683, EXPERIMENTAL LASER MEASUREMENT RESEARCH
H.S. BOYNE, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Boulder, Colorado*

Objective: To investigate the measurement of laser parameters involved with new exploratory laser devices, such as fast flow CO2 lasers, pulsed atmospheric CO2 lasers, and other chemical lasers.

Approach: To design and build a facility for fast flow electric discharge lasers and for high power pulsed CO2 lasers and to investigate the properties of these lasers using various diagnostic techniques.

One possible output of this project could be the development of a convenient computer program for easy use by physical chemists and which will be able to use short excerpts of existing tables (such as JANAF tables) for thermodynamic functions in computing equilibria for pollution constituents.

A possible second output, whose importance will depend on the densities of interest in the processes studied, may be an easy to use computer program which predicts intermolecular potentials from known empirical rules, for such possible pollutants as may have thermal functions included in the JANAF tables.

1.0684, CONSULTATION AND ADVISORY SERVICES FOR ROCKET-BORNE CRYOGENIC WHOLE AIR SAMPLER
J. HORD, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Boulder, Colorado*

Consultation and advisory services on air-sample modifications continue on an as-needed basis. Examples are advice on the selection and placement of instrumentation, selection of construction materials for both high and low temperature service, selection of thermal insulation materials, and review of designs pertaining to fluid flow, fluid phenomena, heat transfer, and structural strength and stability.

SUPPORTED BY U.S. Dept. of Commerce - N.B.S.

1.0685, HIGH RESOLUTION IR ABSORPTION SPECTRA OF GAS POLLUTANTS AT AMBIENT CONDITIONS AND TO INCLUDE SO2, NO, NO2, NH3, HNO3, C2H4 INITIALLY
J.S. NADER, U.S. Dept. of Commerce, Wave Propagation Laboratory, *Boulder, Colorado* 80302

Basic information on the IR absorption spectra of pollutants at high resolution will be obtained from controlled laboratory experiments. A model of a simulated atmosphere and the expected spectra will be developed to correspond to an urban atmosphere containing a mixture of pollutant gases. This data will be used to analyze the empirical spectra observed in the field under various environmental conditions. It will also provide a basis for design and performance criteria of IR spectroscopic instrumentation for measurement of specific pollutants.

1.0686, SUB-MILLIMETER RESEARCH
UNKNOWN, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302 (011667)

1. AIR QUALITY

(1) Development of coherent radiation techniques in the submillimeter and infrared. (2) Development of methods for remote sensing of atmospheric components.

(1) Continue spectroscopy of H2O in the range of 550 to 650 GHz. (2) Complete Stark effect measurement and dipole moment calculation of D2O And H2O. (3) Develop dye lasers for laboratory Raman resonance studies. (4) Perform field experiments using Raman lidar to prove feasibility of water vapor profile measurement. (5) Field experiment using HCN laser to measure humidity fluctuations. (6) Laboratory search for resonance Raman effects.

(1) Generation of coherent sub-millimeter wave power at 600 GHz. (2) Measurement of 3 sub-millimeter wave water transitions near 600 GHz. (3) Laboratory measurement of water vapor content by use at 311 and 337 micron laser lines. (4) Development and publication of theorems on the Fabry-Perot resonator. (5) Lidar System Study for NESC. (6) Haswell field experiment showing passive infrared correlation of water vapor emission by crossed beam radiometers. (7) Measurement of relative Raman cross section of H2O , O2 and CO2.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

1.0687, MEASUREMENTS FOR AIR QUALITY
B. WOODWARD, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Boulder, Colorado*

Objective: To study various scattering mechanisms to determine significant parameters such as density, size distribution, and chemical composition of particulate matter and foreign gases in the atmosphere.

Approach: The present approach is defined by three experiments (1) differential scattering and polarization experiments to determine particulate size distribution; (2) Raman scattering in an attempt to identify the constituents in an atmospheric aerosol; (3) absolute Raman cross section measurements to be used as a standard for determining concentrations of foreign gases in the atmosphere.

Outputs Expected: Publications, Improved Measurement Techniques for determining air quality parameters.

SUPPORTED BY U.S. Dept. of Commerce - N.B.S.

1.0688, DISTRIBUTION OF NITRIC ACID IN THE STRATOSPHERE
D.G. MURCRAY, Univ. of Denver, School of Arts, *Denver, Colorado* 80210

The objective of this research is to determine the distribution of HNO 3 with altitude at various times of the year in order to determine whether or not HNO 3 is a variable constituent of the atmosphere. These data are obtained by performing a series of balloon flights at various times of the year with instrumentation designed to measure the atmospheric emission due to HNO 3 as a function of altitude. It is expected that the SST flights will affect the quantity of HNO 3 in the stratosphere; thus, measurements of this quantity are being made before the occurrence of extensive SST flights.

SUPPORTED BY U.S. National Science Foundation

1.0689, ATTENUATION OF THE SOLAR BEAM BY POLLUTION IN THE BOUNDARY LAYER OF AN URBAN ATMOSPHERE
W.E. REIFSNYDER, Yale University, Graduate School, *New Haven, Connecticut* 06520

This grant is for support of measurements of the effects of the urban atmosphere on the solar radiation which is received at the earth's surface.

The experiments will investigate the loss of direct solar radiation at street level from approximately 100 meters in height in downtown New Haven, Connecticut.

Clock driven pyrheliometers with changeable filters will monitor the magnitude spectral quality and variation of the solar beam. Selected pollutants will be monitored concurrently and an attempt will be made to use solar radiation measurements as a means of monitoring pollution concentration.

SUPPORTED BY U.S. National Science Foundation

1.0690, ATTENUATION OF THE SOLAR BEAM BY POLLUTION IN THE BOUNDARY LAYER OF AN URBAN ATMOSPHERE
W E. REIFSNYDER, Yale University, School of Forestry, *New Haven, Connecticut* 06520

The problem is to describe the attenuation of direct beam solar radiation through the lowest layers of an urban atmosphere. Primarily through the processes of scatter and absorption, the intensity of the solar beam is reduced as gaseous and particulate atmospheric constituents are encountered. Solar radiation at normal incidence will be monitored by three matched pyroheliometers installed on clock-driven equatorial mounts at three elevations within urban New Haven, Connecticut. Filters will be used to break the solar spectrum into several wavebands, and the magnitude, spectral quality and temporal variability of the direct solar beam will be determined.

Several air pollutants will be monitored concomitantly with the radiation measurements; the relation between solar beam attenuation and air pollutant concentrations will then be examined. An attempt will be made to develop methods of continuously monitoring pollutant loading using measurements of solar beam attenuation in the surface layer.

1.0691, ANALYSIS OF CREW STATION BREATHING ATMOSPHERES
C.E. KUYATT, U.S. Dept of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

Technical Objective: The analytical detection of trace gas contaminants in critical environments, such as manned missile silos and launch control centers, is continually frustrated by the need for remotely located, sensitive and stable instruments. Current technics utilize a variety of instruments; chromatography, mass and infrared spectrometry and combinations, each of which has its own vagaries and limitations. The purpose of this effort is to test and evaluate ESCA, (electron spectroscopy for chemical analysis), a new analytical tool for the combined analysis of not only major respiratory gases but also trace contaminants found in breathing gas mixtures.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0692, FEASIBILITY STUDIES TO DETERMINE THE USE OF VARIOUS MATERIALS AS STANDARD REFERENCES FOR AIR POLLUTION MEASUREMENTS
J. MARGESON, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

Evaluate materials and means of generating atmospheres for use in evaluating and collaboratively testing of methods used in measuring sulfur compounds, particulates (filters, etc,), oxidants, CO , hydrocarbons, aldehydes, Pb, fluorides, and polynuclear aromatic compounds. These pollutants will be included in CPA-70-40 and NBS certification as needed by the contractor will be required to meet the needs for methods as established by the issuance of Air Quality Criteria Documents and the publication of Standards in the Federal Register. Priorities will be established by NAPCA to meet needs of the system being developed to evaluate and collaboratively test methods recommended for air pollution measurement.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0693, DETERMINE THE FEASIBILITY OF USING NO2 PERMEATION TUBES AS PRIMARY STANDARDS FOR TRACE GAS ANALYSIS
J. MARGESON, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

Evaluate and establish NO2 permeation tubes as primary standards for trace analysis of nitrogen dioxide. Pursuant to this the contractor shall statistically evaluate permeation rates as in-

fluenced by environment and usable variables such as temperatures, relative humidity, storage, and hysterisis. Guidelines will be established from the analysis of previous data from a feasibility study for SO2 permeation tubes. Priorities and time schedules will be established by the NAPCA to meet requirements of the system being developed to evaluate and collaboratively test methods recommended for measuring NO2 by the SAC and the ISC. Certification of NO2 permeation tubes as standard reference materials for trace gas analysis is expected.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0694, AERONOMY AND OTHER ATMOSPHERIC STUDIES

A.E. GREEN, Univ. of Florida, School of Arts, *Gainesville, Florida* 32601

The development of photoelectric and photographic measurements of the sun's aureole will be continued to provide a simple basis for monitoring atmospheric aerosols. In particular it is proposed to expand the applicability of present methods to a wider range of atmospheric conditions, giving greater attention to multiple scattering. This might allow application of analysis to hazy or overcast days. The effect of light scattered by clouds in a otherwise clear sky will also be investigated.

Present aerosol models acould be improved considerably if a direct means of assessing aerosol structure at different altitudes were available. Passive sky brightness studies will be coordinated with (separately funded) studies under Prof. R. S. Sholtes of the Dept. of Environmental engineering at the University of Florida using an aircraft, equipped with a particle sizing-counting instrument. This research will also be coordinated with a (separately funded) program of assessing atmospheric aerosols by bistatic lidar under Prof. Gray D. Ward of the Department of Physics and Electrical Engineering. Correlation with other remote sensing techniques is also under consideration. Theoretical and experimental studies of the emission of the earth's atmosphere in the near infra-red will also be pursued.

Techniques for determining plasma transport velocity will be applied towards an extensive and systematic study of the diurnal and seasonal behavior of plasma transport including the effect of magnetically disturbed conditions.

SUPPORTED BY U.S. National Science Foundation

1.0695, MIXING DEPTH

R. MCCALDIN, Univ. of Florida, School of Engineering, *Gainesville, Florida* 32601

Aircraft sampling of meteorological and air quality parameters will be made to describe synoptic scale weather features with respect to air pollution potential conditions. An evaluation of present techniques to determine mixing depth will be completed. A description of the time- space variation of pollutants suspended in a given air mass will be attempted from aerometric measurements.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0696, A NUMERICAL MODEL OF THE SEA-BREEZE CIRCULATION

J.E. GEISLER, Univ. of Miami, School of Marine Science, *Miami, Florida* 33149

It is anticipated that numerical models will become an indispensable tool in the study and control of urban air pollution. In coastal areas, a model which is intended to describe the dispersal of pollutants must also describe or reflect the sea-breeze circulation. Since such a general numerical model would be complex in other respects, the simplest possible scheme describing the sea-breeze circulation should be incorporated. An objective of the proposed research is to establish just what constitutes the simplest possible scheme. In the actual forecasting of urban pollution in a coastal area, the question of whether or not a sea breeze will flood the area on a given day is a crucial one. A further objective of the proposed research is to establish criteria which can be used to forecast when and where the sea- breeze circulation will develop and how far the sea breeze itself will penetrate inland.

The immediate objective of the proposed research is to develop a numerical model of the sea-breeze circulation. The model will be used in an effort to establish the dependence of the extent and intensity of the circulation upon the depth of the heated layer over the land; the degree of viscous drag over the land; the details of the thermal stratification of the atmosphere; and the prevailing synoptic-scale flow. As far as possible, the effects of each of these factors will be examined separately, with the explicit purpose of associating a particular type of sea-breeze circulation with a particular set of governing circumstances. Forecasting criteria will be inferred from this association, and the effect of progressively simplifying the model will be assessed.

1.0697, ATMOSPHERIC CHEMISTRY OF BORON

R.C. HARRISS, Florida State University, School of Arts, *Tallahassee, Florida* 32306

Boron is potentially a major pollutant in the atmosphere. The few analyses available for boron in atmospheric precipitation show levels in highly traveled areas to be at least one order of magnitude higher than samples from remote locations. Because of the possible adverse biological effects of boron contamination of the atmosphere and the many potential applications of analytical data on atmospheric boron in meteorological and oceanographic studies research on the sources, distribution, and removal of boron from the atmosphere should be initiated. However, the available spectrographic and colorimetric analytical methods for boron are not suitable for the low levels of boron in atmospheric precipitation and aerosols and are too long and tedious for the large scale investigations required to elucidate the atmospheric chemistry of boron. The proposed investigation will have two specific objectives. These are: (1) To develop a specific ion electrode procedure for the analysis of boron in atmospheric precipitation and aerosol samples. The electrode when combined with preconcentration by ion exchange would be sufficiently sensitive, rapid, and relatively inexpensive. (2) To initiate studies on factors controlling the natural levels of boron in atmospheric precipitation with particular emphasis on the mechanism of transfer across the sea-air interface.

1.0699, FIELD MEASUREMENTS OF ATMOSPHERIC TURBULENCE

P. FRENZEN, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

The structure of turbulence near the ground is being studied to develop simpler methods for measuring vertical turbulent exchanges of momentum, heat, and moisture. Turbulence mechanisms involved affect local problems such as pollutant dispersion and evaporation, while on the global scale they accomplish virtually all the atmosphere's useful energy imput and account of half the system's frictional losses. Thus, a further objective seeks to parameterize the fluxes in terms of ordinary meteorological variables to facilitate incorporation of these lower boundary conditions in numerical forecast models.

Turbulent fluctuations of wind, temperature, and humidity are recorded over uniform sites, using specially developed instrumentation. Vertical fluxes are evaluated indirectly by integration of high- frequency signal variance and directly by eddy correlation procedures. A portable digital computer has been developed to compute fluxes by both methods in real time. Because of relative insensitivity to platform motions, the indirect method is especially suited to the analysis of observations taken over large bodies of water.

1. AIR QUALITY

Results: Experiments conducted over extensive, uniform land sites in Australia and over the open sea during BOMEX have compared the methods and evaluated requisite numerical constants. Observations at sea, using an instrumented spar-buoy, have detected a marked difference in turbulent energy budgets over water as compared to those over land. Further observations over water (Lake Michigan) are being prepared.

1.0700, CONTINUOUS MEASUREMENT OF EFFECTIVE AIR POLLUTION MIXING DEPTH BY MEANS OF SOLAR RADIATION EQUIPMENT

H. MOSES, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-ENG-38)

A technique is being developed which uses two pairs of pyrheliometers on equatorial mounts to measure the height of the aerosol layer. One pair is located on a tall building and another pair, on the ground. One pyrhelimoter of each pair has a 4000-4500 A filter and the other, a 5500-6000 angstrom units filter. Considering ratios of the solar radiation intensity recorded by combinations of the pyrheliometers, it is possible to determine the depth of the aerosol mixing layer under the assumption that the aerosols within it are approximately uniformly mixed. Variations from a uniform aerosol distribution can be handled when 3 or 4 pairs of instruments are used at various heights with the greatest height approaching 1,000 ft.

A correlation technique is also being considered involving the intersection of the fields of view of two pyranometers. One pyranometer has a conical field of view of about 1 degree which is directed upward. The second, also with a narrow field of view, is located about 1,000 to 2,000 ft. away. This pyranometer is designed to scan by changing its elevation angle so that the height of the common volume of the two intersecting fields of view varies from a level near the ground to several thousand feet above ground. The covariance between the signals recorded by the two instruments would change as the common volume passed from dirty to clean air. By noting the height at which changes occur, it should be possible to determine both the height of the aerosol mixing layer and the presence of aerosol layers above the primary ground-based layers.

Results: No measurements have been made to date. Equipment is being assembled to determine the mixing depth by the method using pairs of pyrheliometers with filter. The associated mathematics has been worked out.

1.0701, BENDIX MULTI-CHANNEL IR SPECTROPHOTOMETER DEVELOPMENT FOR LONGPATH MONITORING OF OZONE

J.S. NADER, Bendix Corporation, *South Bend, Indiana* 46620

This is a research instrument development for field utilization, designed for both longpath IR absorption spectroscopy (active mode of operation) and for remote IR emission spectroscopy (passive mode of operation). The instrument system is designed to operate by programmed instructions from built-in computer that also analyzes the spectral data collected and give a pollutant concentration readout. Programming also crrects for interfering pollutants. The instrument is capable of analyzing for any other pollutant having absorption spectra in its IR spectral range from 7 to 14 microns. However, to do so, it is necessary to have the computer programmed for the pollutant of interest. This development is designed with a computer program for measurement of ozone over a longpath. Number of channels of information collected and utilized can be arbitrarily set in the instructions to the computer to degrade performance of instrument to the minimum channel number consitent with the required accuracy of measurement required. Thus, for prototype field instrument development, optimization of design can be determined for relatively simple and inexpensive pollutant detection system.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0702, LOW LEVEL VERTICAL OZONE DETERMINED BY INVERSION OF BACKSCATTERED ULTRAVIOLET RADIATION

D.N. YARGER, Iowa State University, Graduate School, *Ames, Iowa* 50010

The purpose of this research is to develop and evaluate a practical means of determining and monitoring the vertical distribution of ozone from satellite measurements. Two methods for inverting the radiation transfer equation in order to determine the vertical distribution of ozone in the atmosphere will be investigated. Because the region of interest is below 10 mb, both multiple scattering and polarization will be considered in the numerical solution.

Numerical procedures will be used for the investigation using computers at Iowa State University and NCAR.

SUPPORTED BY U.S. National Science Foundation

1.0703, SPREADING OF LEAD IN RURAL AREAS

E.B. BUCHANAN, Univ. of Iowa, School of Arts, *Iowa City, Iowa* 52240

Trace concentrations of metallic components in suspended particulates and dustfall constitute a significant aspect of air pollution. In essentially rural areas the deposit of lead along well-travelled highways provides a unique, although neglected, opportunity for a gradient study of the degree and extent of lead pollution. This study correlated with an investigation of the absorption of lead by vegetation can serve to elucidate specific features of the life cycle of a metallic pollutant.

Studies of trace metals require analytical methods of high sensitivity. The first objective of this study, therefore, is to develop rapid, yet sensitive, analytical techniques employing (1) square wave polarography and (2) x-ray emission spectroscopy. Preliminary studies indicate that both the controlled potential square wave polarograph and the x-ray emission spectrograph have the requisite sensitivities for the determination of lead deposits along highways.

The second objective is to elaborate sampling techniques for the collection of particulate matter and vegetation. These techniques need to be related to the gradient nature of the study and to the types of instrumentation.

The third objective is to apply the above instrumentation and techniques for the determination of lead gradients in selected rural areas.

1.0705, INSOLUBLE ION ASSOCIATION COMPOUNDS AS ANALYTICAL REAGENTS

J.L. LAMBERT, Kansas State University, Graduate School, *Manhattan, Kansas* 66502

Dr. Lambert will continue his research in chemistry on a new type of colorimetric reagent. The compounds being studied are insoluble ion association compounds in which at least one of the ions is highly colored and one is selectively reactive toward a particular ion or molecule in solution in low concentration. The reagents are compounds formed between dye cations or anions, metal complex cations or anions, or other large ions. The destruction or structural alteration of the reactive ion of the reagent releases the non-reactive colored ion into solution in direct proportion to the concentration of the substance being determined. Alternatively, chemical attack by a substance upon a colored reactive ion of an ion association reagent may expose a colored

counter ion. This effect is particularly useful in reagents for gas analysis on a cumulative basis, where color change in a dry reagent is produced. The research will consist of the development of new analytical reagents, and fundamental studies on the structures and properties of ion association compounds. Analytical methods based on these reagents are simple, and potentially sensitive and selective. They can easily be adapted to automated procedures for water and air pollution analysis.

SUPPORTED BY U.S. National Science Foundation

1.0706, NEW ANALYTICAL METHODS FOR SULFUR DIOXIDE
J.L. LAMBERT, Kansas State University, School of Arts, *Manhattan, Kansas* 66502

The objective of this research is the development of new reagents for sulfur dioxide in the concentrations normally encountered in air. We have found one class of compounds that appears to be specific for sulfur dioxide, and two compounds that react with several gases in addition to sulfur dioxide. The reaction of the compounds having specificity is reversible and releases sulfur dioxide slowly at room temperature from either the solid compound or its solution. This property has been found useful when the compound is used as a reagent on a quartz oscillator crystal. By means of the piezoelectric effect, a sampling crystal changes frequency linearly with gain in mass of the reagent compared to the frequency of a reference crystal. Concentrations below O.2 ppm sulfur dioxide have been detected by this method. The frequency change can serve as the basis for telemetry, so that signals from a number of remote sensing devices can be transmitted to a central receiving unit. The reversibility of the reagent-sulfur dioxide reaction makes the reagent self-renewing and thus would reduce maintenance on the sensing devices.

1.0707, THE DIRECT AND CONTINUOUS DETERMINATION OF METALS IN AIR
J.W. ROBINSON, Louisiana State University, School of Chemistry, *Baton Rouge, Louisiana* 70803

During the next twelve month period we intend to investigate the applicability of our equipment to the direct determination of mercury and cadmium in the atmosphere. Specifically, we intend to determine the analytical sensitivities of these elements and to study the effect of the chemical form of the metals in the atmosphere for possible interferences on the absorption signal. This directly affects the accuracy of the analytical method. In addition, we shall prepare calibration curves.

These problems are particularly difficult to deal with because of the very low concentrations of metals involved (10 to the minus 12th power g).

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0708, SELECTIVE AND SENSITIVE METHODS FOR THE DETERMINATION OF SULFURIC ACID AEROSOLS
P.W. WEST, Louisiana State University, School of Science, *Baton Rouge, Louisiana* 70803

Dr. West will work on the development of improved methods for the determination of sulfuric acid aerosol and for sulfate particulates for application in air pollution studies. The principal effort will be directed toward the quantitative reduction of SO sub 3 to SO sub 2. The resultant sulfur dioxide will be trapped in the form of the stable sulfitodichloromercurate(II) complex and subsequently measured spactrophotometrically through the use of prosaniline hydrochloride. A secondary effort will be directed toward the complete reduction of sulfuric acid and sulfates to sulfide with subsequent conversion to methylene blue for quantitative measurement. In addition to chemical methods, electroanalytical procedures will be studied based on the development and use of ion selective sulfate electrodes.

SUPPORTED BY U.S. National Science Foundation

1.0709, USE OF SOLID STATE DETECTORS IN AIR POLLUTION RESEARCH
G.G. GUILBAULT, Louisiana State University, School of Science, *New Orleans, Louisiana* 70122

A study will be made of the use of solid state devices, such as the piezoelectric crystal and the contact potential detectors, for the detection and determination of inorganic and organic substances of importance in air pollution. Promising adsorbents will be placed as coating on the solid state devices, and each detector will be evaluated with respect to sensitivity and linearity of response, accuracy of response, speed of response, limits of detection, stability, simplicity of design and selectivity of response.

By use of these detectors with the choice of proper adsorbents, methods will be developed for the assay of HF, Osub3, SOsub2, NO, NOsub2, CO, trace metals (Pb, Ti, Ni, etc.), hydrocarbons and other atmospheric pollutants.

1.0713, TRANSPORT, DEPOSITION, AND METEOROLOGICAL STUDIES OF NUCLEAR DEBRIS IN THE ATMOSPHERE
L. MACHTA, U.S. Dept. of Commerce, Air k sources Laboratory, *Silver Spring, Maryland* 20910 (AT(49-7))

The research aims at improving techniques for predicting the distribution, transport and deposition of radioactive debris in the atmosphere while simultaneously using these tracers to in-

vestigate atmospheric processes. Over the years, balloon, aircraft and surface sampling systems have provided data on various radioactive tracers resulting from nuclear testing, from other atmospheric inputs and from natural processes. These tracers have been used to construct models of the stratosphere circulation, of stratospheric-tropospheric exchange, of interhemispheric mixing and of the expected time and latitudinal distribution of the deposition of debris injected into the stratosphere. Recent French and Chinese megaton-range nuclear tests provide new information on the stratosphere and the rate of interhemispheric exchange. Tracer data is also being prepared for use in sophisticated numerical models of the atmosphere to test the validity of the model and to use the results for predictive purposes. A technique for estimating large-scale precipitation scavenging using data on the naturally produced cosmogenic radioisotopes, Ar-37, a noble gas and Be-7, a particulate, appears promising. Improvements in balloon technology and in high-altitude sampling capability continue. A molecular sieve C-14 sampler capable of obtaining CO2 samples up to 40 km is being developed and tested.

Results: Fission product ratios, used to identify French and Chinese debris, have provided new information on the structure of the Hadley cell and have suggested that the Hadley circulation extends into the stratosphere. The surface of maximum concentration of straospheric debris has been shown to slope downward from the equator to the pole, and to eventually attain similar slopes irrespective of the nature of the initial stratospheric input. The C-14 sampler is now available for operational use.

1.0718, FEASIBILITY OF RAMAN SCATTER TECHNIQUE FOR REMOTE MONITORING OF NO AND SO2 IN STACK EMISSIONS
D. LEONARD, Avco Corporation, *Everett, Massachusetts*

A two phase study is underway to determine if Raman scatter technique is feasible for remote sensing of NO and SO2 in power plant stack emissions. It is aimed primarily at NO detection since IR techniques are not presently applicable due to the presence of water vapor as an interference. The method also lends itself to SO2 measurement which, however, can be measured by IR methods. The first phase is a laboratory study to determine Raman scatter cross-sections. The second phase is to assess the feasibility of the method with a breadboarded instrument system in the field under environmental conditions of actual power plant plumes. Results will be the basis of design and performance criteria to be set up for the development of a prototype instrument assuming the feasibility is within the current state-of-the-art in laser technology and Raman scatter detection.

1.0719, ENGINE EXHAUST EMISSIONS MEASUREMENT SYSTEM
D.A. LEONARD, Avco Corporation, *Everett, Massachusetts* (F33615-71-C-1875)

Technical Objective: Develop a system based on laser raman spectroscopy for simple, real time, non-interference measurement of carbon monoxide, carbon dioxide, oxides of nitrogen, organic and other exhaust emissions from aircraft gas turbine engines. Program is to produce an engineering prototype as a technology feasibility demonstrator.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0720, CONTINUOUS CHROMATOGRAPHIC MONITORING OF GAS STREAMS
M.V. SUSSMAN, Tufts University, School of Engineering, *Medford, Massachusetts* 02155

A new gas chromatography technique which permits continuous introduction of mixtures and simultaneous continuous withdrawal of purified fractions and which uses no packing has recently been demonstrated by the principal investigator. The technique has high capacity and fractional second response. Potentially it can monitor air or waste gas streams, both detect and isolate air pollutants.

An investigation aimed at adapting this technique to monitoring of gas streams for air pollutants is under way.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0721, KRYPTONATE-BASED INSTRUMENTATION DEVELOPMENT FOR AUTOMOBILE EXHAUST POLLUTANTS
P. GOODMAN, Panametrics Incorporated, *Waltham, Massachusetts* 02154 (AT(30-1)-4069)

Instrumentation for the analysis of automobile exhaust pollutant concentrations is required for a number of purposes, important among which is the determination of the efficiency of operation of installed emission control devices, i.e., an inspection function. Among the deficiencies of instrumentations currently in use is the fact that they are derivatives of instrumentations currently in use is the fact that they are derivatives of sophisticated laboratory-type instruments and consequently require trained personnel for operation. A program is in progress whose ultimate objective is the development of an instrument utilizing kryptonates for automobile exhaust pollutant analysis. Such an instrument would utilize a single principle for the detection of carbon monoxide, hydrocarbon and nitrous oxides and could be employed by service-type personnel during periodic or random inspection.

A second phase of this development program has recently been initiated which will involve construction of a breadboard instrument, optimization of instrumental design parameters, characterization and calibration of the instrument and testing of the instrument during field operation.

Results: An initial feasibility study of this instrumental concept has been completed. Shown in a laboratory test system was the capability for detection of 125 ppm of CO by means of a Pd c1 2 kryptonate and 2 ppm of nitrous oxide by means of a hydrogen clatrate. Hydrocarbons were detected by a Pt O2 kryptonate at the 13 ppm level for propane but with a sensitivity which increased with the hydro-carbon molecular weight. Detection thresholds are considerably below projected future national emission standards for automobile exhaust pollutant emissions. Interferences were absent.

1.0722, GAS CHROMATOGRAPHY AND AIR POLLUTION CONTROL
Y.H. MA, Worcester Polytechnic Inst., School of Engineering, *Worcester, Massachusetts* 01609

Since both adsorption of pollutants to harmless or readily absorbed forms are two methods proposed for control of pollution, and since the adsorption isotherms and effective diffusivities are primary factors for these processes, a rapid and simple technique for their determination would be of inestimable valuable. The proposed method of gas chromatography in obtaining simultaneously the adsorption and diffusion data is potentially much more rapid and the necessary equipment simpler than those currently in use. It should be emphasize that combining two measurementr in a single piece of equipment has not been attempted previously. It should also be emphasized that by its very nature the proposed method of measurements involves the competitive adsorption of the carrier gas and the adsorbate (pollutant) and the adsorbate concentration is small. Accurate data for such conditions are difficult to obtain by the usual vacuum technique and extremely important for pollution control.

1.0724, DIESEL IGNITION AND COMBUSTION ENGINE RESEARCH
J. BOLT, Univ. of Michigan, Graduate School, *Ann Arbor, Michigan* 48104 (DAAE07)

Technical Objective: Research objective is to obtain basic information concerning critical parameters and durability on the combustion process under high temperature operating conditions. Areas of greatest interest are ignition delay, exhaust gas pollutant measurements and emission tests.

SUPPORTED BY U.S. Dept. of Defense - Army

1.0725, THEORETICAL INVESTIGATION OF INFRARED RADIATIVE TRANSFER
S.R. DRAYSON, Univ. of Michigan, School of Engineering, *Ann Arbor, Michigan* 48106 (011742)

Progress: Detailed spectra of the CO2 15 band are being obtained at the Willow Run Laboratory of the University of Michigan with a resolution of about .06 cm super minus 1. From these spectra a table of line positions is being prepared and often shows significant departure from previously accepted measurements. Spectra of CO2 isotopes common in the atmosphere are also being evaluated. This data will be incorporated in future calculations of atmospheric transmittance.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

1.0726, ADAPTATION OF OXIDES OF NITROGEN ANALYTICAL METHOD TO LIGHT DUTY VEHICLE EXHAUST EMISSION PROCEDURE
G. CAHILL, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ypsilanti, Michigan* 48197

Total nitrogen oxides instrumentation recommended by BEPS will be evaluated to determine its compatability with the 1972 Federal Test Procedure. Tests to determine correlation with the current California NQx test procedure will be run on uncontrolled vehicles. A draft of proposed regulations will be prepared.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0727, DEVELOPMENT OF PARTICULATE EMISSION PROCEDURE
R.E. KRUSE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ypsilanti, Michigan* 48197

Preliminary tests will be performed to determine the best sample point on a constant volume sampler and its acceptability by comparison to a total particulate sampling method. The need for specific vehicle preconditioning and the effect of exhaust system age will be investigated. A procedure compatible with the 1972 test procedure will be developed.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0728, COLD START SURVEILLANCE TESTS OF NEW VEHICLES
R.W. OLSON, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ypsilanti, Michigan* 48197

Conduct (1) cold-start surveillance tests of new vehicles to determine exhaust emissions differences between 'green' vehicles and 'broken-in' vehicles; (2) inspection tests on selected vehicles; (3) smokemeter tests on heavy-duty diesel trucks at idle and free-acceleration conditions.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0729, CONDUCT EMISSION TESTS ON DEVICES
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Ypsilanti, Michigan* 48197

Conduct emission tests on devices, engines, and vehicles to determine the ability to meet 1972, 75 or 1980 standards depending upon the contractual requirements. These evaluations require repetitive testing and in some cases they require adaptation of existing equipment and analytical methods to unique power sources.

1.0730, STUDY THE LEVELS OF POLYCYCLIC HYDROCARBONS IN AN URBAN ATMOSPHERE
UNKNOWN, Univ. of Minnesota, Graduate School, *Minneapolis, Minnesota* 55455 (NIH-70-2058)

Independently, and not as an agent of the Government, the Contractor will exert its best efforts to design and construct an air

sampler for the chemical detection of polycyclic hydrocarbons in the urban atmosphere. More, specifically, the Contractor shall: 1. Review literature concerning air sampler design and chemical detection of polycyclic hydrocarbons. 2. Design and construct an air sampler. 3. Determine the aerosol characteristics of an air sampler along with the efficiency in controlled atmosphere. 4. Evaluate the sampler's performance under ambient sampling conditions. 5. Set up atmospheric sampling program. 6. Maintain weather equipment so that weather information is available. 7. Develop chemical detection procedures. 8. Develop standards for quantitative chemical analysis. 9. Collect samples according to predetermined plan. 10. Analyze samples for polycyclic hydrocarbons present. 11. Analyze and correlate data.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0731, GENERATION AND DECAY OF SMALL IONS
K.T. WHITBY, Univ. of Minnesota, School of Engineering, *Minneapolis, Minnesota* 55414

During the 71-72 project year the Minnesota Aerosol Analyzing System will be used by Mr. W.E. Clark to measure the changing aerosol size distributions and concentrations of aerosols produced by the photochemical oxidation of SO2. The MAAS will permit Mr. Clark to follow the aerosol from initial formation to sizes in the micron range produced by coagulation and condensation after several hours.

Mr. H. Hansen will use the MAAS to study the condensation and evaporation of water on submicron artificial and atmospheric aerosols.

Work will continue on the development of an aircraft and auto portable MAAS consisting of a Bausch & Lomb optical counter and a new small electrical aerosol analyzer currently being developed. This portable system will make possible the real time measurement of aerosols in 8 size ranges between O.OO7 and 15 microns.

During the early part of the project year Mr. R.B. Husar will finish his theoretical and experimental work on the coagulation Knudsen aerosols.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0732, AEROSOL MEASUREMENTS IN LOS ANGELES SMOG
K.T. WHITBY, Univ. of Minnesota, School of Engineering, *Minneapolis, Minnesota* 55414

As of December, 1969, it now appears highly desirable to continue this project at a low level for two more years.

There are four main obectives for the work to be performed during the next two years. These are: 1. Completion of the data analysis and the proper reporting of this data through reports and papers. It should be noted that the chemical analysis being performed by Dr. Mueller will probably not be completed until the end of 1970. 2. The carrying out of a few supplementary laboratory experiments to provide data useful in the interpretation of the Los Angeles data. These will consist mostly of coagulation experiments with small aerosols under conditions designed to simulate the distributions observed in Los Angeles. 3. The principal investigators in the Los Angeles project, that is Dr. Friedlander, Dr. Hidy, Dr. Mueller, and Dr. Charlson, as well as others such as Dr. Jim Friend of New York University and Dr. Christian Junge of Germany, have all expressed an interest in participating in a further project of this sort to be carried out perhaps in 1972 or 1973. A portion of the time during the second year would be used to study the where, when, and how of such a project. If a decision is made to perform such a project, a separate proposal for it would be submitted. 4. After the humidity control system for the MAAS is developed and operating, we are planning on using the MAAS and the Lundgren impactor to make some further measurements of urban aerosol in Minneapolis, mostly as a means of exercising the new techniques in preparation for any larger project which may follow.

1.0733, CONTINUOUS PARTICULATE MONITORS FOR FOSSIL FUEL COMBUSTION SOURCES
G. SEM, Thermo Systems Incorporated, *Saint Paul, Minnesota* 55413

Objective: Completion of research program development and initiation of laboratory studies.

Description: Evaluation of the technical literature and critical review of instrument techniques for applicable techniques to be incorporated in two state-of-the-art reports. One report will be devoted to mass flow techniques and one report for size distribution - number average techniques. The best technique for mass flow measurement will be incorporated in the fabrication of a prototype device. Characterization of fossil fuel emission factors will be acquired as needed to determine instrument specifications.

1.0734, THE CLIMATIC RESOURCES OF THE NORTH CENTRAL REGION
D.G. BAKER, Univ. of Minnesota, Agricultural Experiment Sta., *Saint Paul, Minnesota* 55101 (MIN-25-064)

OBJECTIVE: One objective is to quantitatively characterize the climate of this region for agriculture. The second objective is to delineate the atmospheric conditions conducive to air pollution.

APPROACH: The approach to the first objective will initially be directed toward the climatology of solar radiation. Spatial distribution of radiation will be obtained by analysis of the 19 radiation stations as a regional unit. Temporal distribution of radiation will be determined by the calculation of probabilities of radiation amounts received during each climatological week at the 19 stations. Work done earlier on derived climatic quantities such as growing degree days will be modified to better meet present requirements. The second objective will be dealt with principally by analyzing a special local site which provides meteorological data that will give a 3-dimensional picture of the atmosphere.

PROGRESS: The 2 manuscripts awaiting approval at this time last year have now been published. A third publication is being prepared which will contain information gleaned from the previous publications and the original data. Such things as the frequency of clear and overcast days at each station, probability of receiving given amounts of radiation, the regional distribution of atmospheric transmissivity, and other items will be carried.

SUPPORTED BY U.S. Dept. of Agriculture

1.0735, DETECTION AND ANALYSIS OF PARTICULATE AIR POLLUTION
R.L. REISBIG, Univ. of Missouri, School of Engineering, *Rolla, Missouri* 65401

Urban areas in America are at this moment being blanketed by clouds of man-made as well as natural dust and gaseous materials. The present effect of this pollution on human health is well established. The future effect of air pollution on the delicate thermal balance of the earth's atmosphere may destroy life as we know it today.

There is a need for accurate and reliable instrumentation to measure the concentration of dust. An instrument of this type might be used to monitor fly-ash in the stack gas from a coal burning power plant. Coal fired steam generators employing highly efficient dust arresting equipment must be controlled so that combustion products do not violate air pollution laws. There is presently no effective means for monitoring fly-ash concentrations in smoke stack gas. An instrument of this type could also be used to measure atmosphere pollution caused by dust and gaseous materials. Municipal governments need reliable scientific methods for determining when local air pollution codes are being violated.

The primary objective of the program will be the analytical and experimental evaluation of the radiative extinction properties of a two component system composed of non-reactive dust and air. Preliminary anaysis and experiments indicate that informa-

tion of this type can lead to instrumentation badly needed in the field of air pollution control.

SUPPORTED BY University of Missouri

1.0736, DEVELOPMENT OF ANALYTICAL TECHNIQUES BASED ON HOMOGENEOUS GAS PHASE LUMINESCENT REACTIONS
UNKNOWN, Monsanto Company, *Saint Louis, Missouri* 63166

Active inhouse and contractual research has led to the partial development of several gas phase chemiluminescent reaction devices, capable of measuring SO2, CO, oxides of nitrogen, singlet oxygen and ozone. Continued research in this area will provide working prototype analyzers for evaluation and comparison with classical methods of measuring these pollutants.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0737, ATOMIC ABSORPTION SPECTROSCOPY WITH A HIGH TEMPERATURE FURNACE
R. WOODRIFF, Montana State University, Graduate School, *Bozeman, Montana* 59715

Dr. Woodriff will continue his basic research on the development of atomic absorption spectroscopy using high temperature furnaces as a method for trace chemical analysis. To help eliminate problems with blanks and to remove more rapidly and completely the sample from the tube, a new furnace will be built which keeps the tube hot throughout its entire length. In addition, an attempt will be made to cause the plasma to give off sufficiently intense emission spectrum to allow the furnace to be used for simultaneous multi-element determinations. In addition to this basic research Dr. Woodriff will apply this new analytical method to important pollution problems. For example, the method is ideal for analysis of silver iodide in snowfall released by cloud seeding. If a sensitive procedure can be developed in this case, it also will be applied to monitoring air for other particulate contaminants. Finally these element contents of various water supplies in Montana will be determined, and attempts made to correlate results with statewide records of livestock deaths possessed by the Veterinary Department at Montana State University.

SUPPORTED BY U.S. National Science Foundation

1.0738, ESSO - INSTRUMENTATION PLAN DEVELOPMENT
R. BERTRAND, Standard Oil Co. of New Jersey, *Linden, New Jersey* 07036

This project will culminate in FY 1971 with a NAPCA 5-year R/D plan for air pollution instrumentation and related analytical techniques. The scope of the study encompasses a market analysis, needs assessment emphasizing the Federal Government sector and the delineation of an R/D plan to fill gaps. Movies are needed in FY 1971 for two modifications to support a NAPCA instrumentation task force and to reflect decisions of the task force in the final plan.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0739, ANALYTICAL METHODS FOR AROMATICS IN AUTO EXHAUST
E. SAWICKI, Standard Oil Co. of New Jersey, *Linden, New Jersey* 07036

Development of rapid methods of analysis for trace quantities of benzo(a) pyrene, polynuclear aromatic hydrocarbons, phenols, and related aromatic substances in automobile exhaust, with particular attention directed to carcinogens and co-carcinogens. By end of contract year hope to have a GC method for BaP plus a GC method for 6-12 polynuclear arenes.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0740, MONITOR LIGHT DUTY MOTOR VEHICLE EXHAUST EMISSIONS INSPECTION GRANT PROGRAMS
UNKNOWN, State Dept. of Health, *Trenton, New Jersey* 08618

Pilot exhaust emissions inspection programs will be conducted in Washington, D. C. by the Division of Motor Vehicles and Department of Public Health, and by the New Jersey State Department of Health. Data generated using a variety of inspection equipment, methods of inspection, and pass-fail criteria will be analyzed, as a related task, using automatic data processing equipment and appropriate statistical techniques to determine the optimum methods and types of equipment to be recommended in a uniform State inspection code.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0741, CONTROLLED CONVERSION OF GASES INTO DETECTABLE PARTICLES
V.A. MOHNEN, State University of New York, Atmospheric Sciences Res. Ctr., *Albany, New York* 12203

Establish the rate of particle formation from gas phase reactions under a variety of experimental conditions and for a variety of gases and gas mixtures. The particle formation is initiated by photochemical reactions as well as by ion-molecule reactions. This information is used to develop systems for the detection of trace gases by means of gas-to-particle conversion. Such a system consists principally of a converter and a small particle counter (Wilson type cloud chamber with expansion cycle). Special attention is devoted to the utilization of this technique as a new detection system in gas chromatography. The results of this research can be directly applied to gas-to-particle conversion that takes place in urban atmospheres as well as on a global scale (gas-to-particle conversion represents an important sink reaction of various atmospheric gases).

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0742, INFRARED REMOTE SENSING OF AIR POLLUTANTS AND FOREST FIRES
S.H. CHAN, New York University, School of Engineering, *New York, New York* 10453

A combined theoretical and experimental program is proposed to monitor air pollutants and to detect forest fires by infrared remote sensing. The theoretical program will include a systematic analysis of the fundamental radiation transport through the nonhomogeneous, intervening atmosphere between a sensor and the object of interest, while the experimental program will employ a unique multiple-scan interferometer and a highly sensitive radiometer to provide data for use in conjunction with the theoretical work. The result of the present study will not only provide solutions which can be used to determine the concentration of gaseous pollutants and to effectively detect forest fires from the radiance measurement of a remote sensor, but also will provide the means for optimizing existing or future sensor performance.

SUPPORTED BY U.S. National Science Foundation

1.0743, SAE COMMITTEE ON DIESEL AND AIRCRAFT GAS TURBINE EMISSIONS MEASUREMENTS
UNKNOWN, Soc. of Automotive Engrs. Inc., *New York, New York*

Participate in joint activities with aircraft operators, powerplant manufacturers and other government agencies or development of acceptable methods for sampling and characterizing emissions from aircraft and design vehicles.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0744, RADIONUCLIDES IN STRATOSPHERIC AIR
E.P. HARDY, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

The sampling and analysis of stratospheric air involves two separate programs: A. Project Airstream is HASL's study of radioactivity in the lower stratosphere employing RB-57F aircraft. The missions are scheduled for early February, May, August, and November, and cover from 75 degrees N to 51 degrees S latitude in the Western Hemisphere. Air filter samples are collected from 12 to 19 km altitude. B. The High Altitude Balloon

Sampling Program uses balloon-borne filtering devices to collect nuclear debris at altitudes from 24-41 km. Balloon launches are conducted quarterly at 44 degrees N, 9 degrees N, 34 degrees S and semi-annually at 64 degrees N and 22 degrees S. Bi- monthly launches are made at 31 degrees N.

Selected filters from both projects are analyzed for Fe-55, Sr-89, Sr-90, Zr-95, Cs-137, Ce-144, Pu-238 and Pu-239, 240. These programs document concentrations of natural and artificial radionuclides in the stratosphere, establish the seasonal trends as a function of latitude and altitude, determine the removal rates of fission products from the stratosphere, and provide data to test existing models of atmospheric transport, to improve these models or develop new ones.

Results: By January 1, 1969, there were 330 kCi Sr-90 in the world stratosphere with roughly 2/3 in the northern hemisphere. By January 1, 1970, the northern hemisphere contained 250 kCi of Sr-90 and the southern hemisphere 57 kCi. The HASL model of atmospheric transport has been used successfully to compute the seasonal fallout in the northern hemisphere from the 1961-62 tests, but it is less effective in the southern hemisphere. Additional studies are planned to make the model latitude sensitive.

SUPPORTED BY U.S. Atomic Energy Commission

1.0745, RADIOACTIVITY AND TRACE ELEMENTS IN SURFACE AIR

H.L. VOLCHOK, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

The HASL surface air sampling program provides data on the latitudinal distribution of nuclear debris, arrival times of fresh debris, interhemispheric transfer, and differences in air concentrations over land and ocean bodies. Weekly surface air samples are collected at 17 stations approximately along the 80th meridian (west) from 86 degrees N to the South Pole and also at Hawaii and Easter Island. All surface air filters are composited on a monthly basis. One fraction is analyzed for Sr-90, Zr-95, Cs-137, Ce-144, Pu-238, Pu-239, 240, and stable Pb, while total gamma activity and gamma spectrum are measured on another, which is then stored for future reference. This project was started at HASL in January 1963, and is a direct outgrowth of a program initiated by the U.S. Naval Research Laboratory in 1957 and continued through 1962.

Results: An empirical relationship between the monthly average hemispheric surface air concentration of Sr-90 and the amount deposited has been developed. On the average, for every dpm per 1000 cubic meters in northern hemispheric surface air, 3.3 kCi, and in the southern hemisphere, 5.0 kCi, are deposited on ground. With these factors, the global deposition of any 'stratospheric fallout' radionuclide can be estimated, from a small number of surface air measurements.

1.0748, PREPARE AND PUBLISH ANALYTICAL REPORTS ON AEROMETRIC DATA

G. AKLAND, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To analyze in depth the trends and interactions of aerometric parameters and publish findings from these analyses.

Approach: Data will be analyzed for trends and cross interaction characteristics by using statistical techniques. Statistical checks will be used to confirm heuristical constructions involving multiple parameters.

Goal: Publish a journal of interpretive papers on high volume sampling precision, frequency of sampling, etc. and reports on backgrounds and trends in metals, 1957-1965 national air quality trends.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0749, PUBLISH REPORTS ON DEVELOPMENTS IN AEROMETRIC DATA ANALYSIS METHODS

G. AKLAND, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To inform Federal, State and local agencies on latest techniques of analyzing aerometric data.

Approach: Analysis techniques developed by DAQED as part of other projects will be described and published.

Goal: Papers on trends analysis of air quality data and automation of laboratory instrumentation will be prepared and published.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0750, PUBLISH BASIC AIR QUALITY DATA

G. AKLAND, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To summarize and disseminate basic air quality data.

Approach: Information in the National Aerometric Data Bank will be summarized in terms of averages and frequency distributions and published as annual air quality data reports. These reports will present data with a minimum of interpretation in order to disseminate them without delay.

Goal: Publish 1967 Air Quality Data and 1968 Air Quality Data and prepare for publication 1969 Air Quality Data and 1969 CAMP Data.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0751, FIELD PERFORMANCE EVALUATION AND APPLICATION OF BENDIX OZONE MONITOR TO SMOG ATMOSPHERE IN LOS ANGELES

H.M. BARNES, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Delivery of Bendix Ozone Monitor is expected by July or August. This will permit plans to conduct field performance evaluation and application during smog season in Los Angeles in September and October and in conjunction with planned field application of the Convair instrument at same time and location.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0752, START OF FIELD STUDY OF IR EMISSION SPECTRA FROM SO2 IN POWER PLANT PLUMES

H.M. BARNES, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Several research instruments capable of remote sensing of IR emission of pollutant stack gases will be available, Bendix multi-

channel spectrophotometer and Convair continuous scanning spectrophotometer. These will be used in the field to assess the IR emission spectra of SO2 and interfering gases from power plant plumes under various plant operations and environmental conditions. Data from this study will be used to establish design and performance criteria for the development of a prototype field instrument for remote monitoring of SO2 emissions by IR emission spectroscopy.

1.0753, DEFINITION AND ANALYSES OF HIGHER MOLECULAR WEIGHT ALDEHYDES
T.A. BELLAR, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

To create the analytical methodology to analyze higher molecular weight aldehydes. These aldehydes have defied a general analysis but in specific cases have been shown to have extremely high toxicological potential, i.e., benzaldehyde yields peroxybenyl nitrate. Therefore, the definition of the amounts produced and their method of production is critical. Analytical methodology must be developed to analyze automotive and other combustion sources for aldehydes, particularly aromatics of seven carbons and higher. Current technology only extends through eight carbons (DNPH) and does not perform adequately in this application. This information is desperately needed to answer public charges on eye irritation.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0754, BIRMINGHAM SOILING STUDY
N. BELOIN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To support in-house building material soiling study with particulate level.

Approach: To take suspended particulate measurements by Hi-Vol every sixth day and dust fall measurements monthly.

Goal: To determine the particulate levels at three exposure sites in Birmingham, Alabama in order to correlate with soiling data.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0755, PROVIDE TECHNICAL ASSISTANCE TO STATE AND LOCAL AIR POLLUTION GROUPS IN THE OPERATION OF FIELD MONITORING EQUIPMENT
J. BRYANT, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: The instrumentation and field evaluation unit of DAQED will provide information to any State or local air pollution agency on pollutant sensors both old and new.

Approach: Telephone and written communications as well as personal visits will be used to convey operating instruction and evaluation reports from on site evaluation of commercial instruments.

Goal: Provide information on some 5 new continuous air monitoring instruments that have been evaluated to requesting agencies. In addition, technical operating and maintenance assistance will be provided on prototype samples such as the NASN modified cascade impactor and a third-generation gas bubbler apparatus under development.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0756, PROVIDE TECHNICAL ASSISTANCE TO STATE AND LOCAL AGENCIES IN AIR QUALITY SURVEILLANCE ACTIVITIES
J. BRYANT, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Provide non-federal agencies with information on calibration procedures sampling methods, data handling, and other guidance as required in the development of their surveillance programs.

Approach: Requesting state and local agencies will be assisted by telephone or written transmission of information. In some cases, on- site visits will be made by NASN and/or requesting agency personnel.

Goal: Process all requests for various types of air monitoring and technical services. It is estimated that approximately 500 requests will be received.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0757, MONITOR STATE, REGIONAL, AND LOCAL PARTICULATE SURVEILLANCE SYSTEMS
J. BRYANT, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Monitor quality of performance of state, regional and local particulate surveillance programs.

Approach: Set up a particulate sampler at a minimum of one site and operate in parallel with a sampler of the state, regional, or local agency. Utilize Federally employed operators to avoid possible bias. Relocate existing particulate stations where necessary.

Goal: Develop a plan, acquire equipment, and make local arrangement for activation of monitoring network of 200 new stations by end of FY 71.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0758, EVALUATE IMPLEMENTATION PLANS WITH RESPECT TO SELECTION OF MONITORING SYSTEMS AND SITES IN AQCR'S
J. BRYANT, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Help in the evaluation of implementation plans of AQCR's as to adequacy of instrumentation, number of sites and/or regional coverage. Specifications for monitoring equipment, data handling, and analytical methods.

Approach: By personal contact prior to submission and review of submitted written requests and/or documents.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0759, DEMONSTRATION AND TRAINING ON CONTINUOUS AIR SAMPLING INSTRUMENTS
F. BURMANN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Operate a continuous air monitoring station using good procedures and practices for purposes of demonstration. Train students on operation, maintenance, and calibration of instruments, using the instruments set aside for this purpose. Develop operational guides, maintenance schedules, and training notes for specific instrumentation. The public and educational institutions will be invited to visit this facility. Displays and handouts will be prepared to describe the purpose and operation of air monitoring instruments.

Provide 20 trainee weeks of instruction.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0760, FORECAST SUPPORT
J. CLARKE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Evaluate air pollution potential forecasts and model's performance, using available meteorological and air quality data. Particular attention will be given to episode or potential episode conditions.

Provide consultant and special forecast services to NAPCA during episodes. Maintain liaison between NAPCA and Weather Bureau during episodes.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0761, APP-AIR QUALITY COMPARISON
J. CLARKE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Evaluate the performance of models used to forecast APP or predict pollutant concentration distributions, particularly during high APP, by comparing observed air quality data to calculated concentration distributions.

1. AIR QUALITY

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0762, FORECAST DEVELOPMENT
J. CLARKE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Develop quantitative descriptions of air pollution potential through the improved forecasts and description of wind, temperature, moisture, mixing depth, turbulence, and other atmospheric parameters within the planetary boundary layer, and as a function of city size.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0763, DEVELOP A SEMI-AUTOMATED ANALYSIS FOR BENZO(A)PYRENE
J.B. CLEMENTS, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To attempt to develop a semi-automated analysis for BaP which would eliminate costly and tedious hand work and facilitate automated data acquisition.

Approach: An attempt will be made to apply gas chromatography and/or high speed liquid chromatography for the separation and determination of BaP in BSO. Output from either method would be amenable to automatic data handling techniques.

Goal: Develop a rapid chromatographic method for separating and estimating BaP in BSO.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0764, DEVELOP AND EVALUATE A ROUTINE METHOD FOR MEASURING BENZANTHRONE
J.B. CLEMENTS, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop and evaluate a routine manual method for the separation and estimation of the benzanthrone contained in the benzene soluble fraction (BSO) of organic particulate.

Approach: The procedures developed by DCP (Sawicki, Stanley, et al), which involves thin layer chromatographic separation of benzanthrone from the BSO and measurement by spectrophoto-fluorescence, will be routinized. Various methods of separation and efficiency of recovery will be investigated. Application of the developed method to samples collected in the NASN will be carried out.

Goal: To develop, routinize and evaluate a manual method for the analysis of BSO for benzanthrone content and to determine this constituent in quarterly composites from approximately 25 stations of the NASN for 1969.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0765, MEASUREMENT OF VISIBILITY REDUCTION BY PARTICULATES BASED ON OPTICAL PROPERTIES OF URBAN PARTICULATES (ABBREV)
W. CONNER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

A mobile optics laboratory is being equipped to conduct field measurements of optical properties of suspended urban particulates. Measurement will include number size distribution, angular lightscatter, volume lightscatter, mass concentration, and light attenuation. Data collected will be analyzed to provide design and performance criteria for prototype instrument to measure visibility reduction that most favorably relates to mass concentration. Information will also be obtained on a possible simple method of measuring number mean size of suspended particles.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0766, EEI-PHS STUDY ON REMOTE SENSING OF PARTICULATE EMISSIONS FROM POWER PLANT PLUMES--EVALUATION OF PLUME-LIDAR MONITORING SYSTEM (ABBREV)
W. CONNER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

A Lidar System to monitor, remotely, particulate content of Power Plant (and other) sources is being built on contract under EEI support, and is scheduled for delivery in late December, 1970. A field performance evaluation of the system will be conducted during the rest of the fiscal year for optical transmission measurement of plumes. This is a high powered laser system that will be used as a research instrument with capability to assess remote measurement of particulate by two different methods. One is the optical transmission property of the plume based on attenuation of laser radiation scattered by the background beyond the plume. This has been demonstrated to be feasible but requires a high powered, complex and expensive system. The other possible method is an evaluation of the radiation scattered back directly by the plume. Such a method, to be developed, will lend itself to relatively low-powered and inexpensive laser system for field use. This research instrument will serve to develop data for design and performance criteria of a prototype field instrument for control agency use.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0767, FIELD APPLICATION OF DIRECT LASER BACKSCATTER FROM PLUME PARTICULATE FOR DEVELOPING DESIGN & PERFORMANCE CRITERIA FOR FIELD INSTRUMENT (ABBREV)
W. CONNER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The Lidar backscatter research instrument of the EEI-PHS Cooperative Study will be modified or adapted as required to apply the direct backscatter technique, developed under contract, in the field. The field application study will be directed to collect data on power plants under a variety of operating and environmental conditions. The data will be analyzed to provide design and criteria for the development of a prototype field instrument for use by control agencies in remote monitoring of particulate emissions.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0768, EMISSION INVENTORIES OF FEDERAL FACILITIES IN AQCR'S
J.E. FLANAGAN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Staff engineers, assisted by engineering aides, collect, verify and analyze emission data on fuel burning and refuse disposal practices at each individual Federal installation in designated AQCR's. The facilities listing is cross checked against the GSA real property listing to assure as complete an inventory as feasible. Collected data are coded, key punched and computer processed, utilizing appropriate factors, to calculate the emissions of particulates, SOx, NOx, HC and CO. Visits to installations are an essential part of this task.

The first 16 of the original listing of 57 AQCR's will be completed in FY 70, and the next 20 are planned for FY 71.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0769, TURBIDITY NETWORK
E. FLOWERS, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Forty (40) observational stations, that measure atmospheric turbidity (at wave lengths of 3500 Angstrom units and 5000 Angstrom units as a measure of the aerosol content of the atmosphere, are maintained in the U.S.; additional observations are obtained from India, Israel, Australia and Hawaii.

Network measurements are analysed with respect to air quality and urban-rural differences in the attenuation of solar radiation by air pollutants. A continuing program since 1960 is providing data to help establish climatological trends in air quality.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0770, OPERATE NATIONAL PARTICULATE NETWORK AT AN INCREASED SAMPLING FREQUENCY
M. GEORGEVICH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Increase sampling frequency in all AQCR's who have implementation plans and standards accepted in compliance to air quality act as amended.

Approach: Sampling eventually will be at a frequency of 100 to 120 samples/year/site. Additional equipment will be provided so that samples can be taken every third day. Employ Federal operators to avoid complications.

Goal: Begin sampling every third day in 20 AQCR's which have established standards.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0771, OPERATE A SPECIAL PARTICULATE NETWORK UTILIZING MEMBRANE FILTER SAMPLERS

M. GEORGEVICH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Collect air samples in support of present and future criteria on trace metals, asbestos, and other special compounds that cannot be obtained from glass fiber filters. Provide air quality and background information on these elements and/or compounds.

Approach: Samples are collected on membrane filters at a sampling rate of 0.15 m3/sec.

Goal: Collect samples from approximately 55 sites 26 times per year.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0772, OPERATE A NATIONAL NETWORK FOR INTERMITTENT SAMPLING OF GASEOUS POLLUTANTS

M. GEORGEVICH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Collect gaseous pollutants nationwide to assess the air quality and for use in the publication of future and/or revised criteria documents. Data can also be used to determine compliance to standards in those regions where standards have been established.

Approach: Gases will be collected utilizing a gas-bubbler absorptive technique. Samples are collected over a 24-hr. period and returned to the laboratory for analysis.

Goal: SO2, NO2, and Hg (not at all sites) will be sampled 26 times per year at 190 sites throughout the nation.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0773, OPERATE A NATIONAL GLASS-FIBER PARTICULATE NETWORK

M. GEORGEVICH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Collect total suspended particulate (TSP) for subsequent analysis. The TSP and other analytical information obtained from the filter will be used to help assess the air quality of the nation and for use in the publication of future criteria documents.

Approach: The TSP will be collected on a random statistical basis by hi-volume samples over the US and territories.

Goal: Collect 26 samples per year from each of 250 urban and non- urban sites over the U.S. and territories.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0774, APPLICATION OF REMOTE SENSING METHODS IN DETECTING AIR POLLUTION DAMAGE TO VEGETATION

D.G. GILLETTE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Develop and evaluate the use of remote sensing techniques in assessing air pollution damage to vegetation.

Approach: The techniques applied in assessing the damage through aerial photography and multispectral scanning devices in the San Bernardino Mountains will be applied in other areas where the pollutants causing the damage and the vegetation may be varied. Resources to conduct this work are supplied by the U.S. Forest Service which has had extensive experience in the use of remote sensing in assessing vegetative damage. In cooperation with TVA, the Forest Service will assess the feasibility of using remote sensing techniques in assessing vegetative damage from SOx around power plants.

Goal: Develop recommendations on the usefulness of various remote sensing techniques in assessing vegetative damage in the TVA area and the extension of this tool to estimate losses in other California Forests.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0775, LABORATORY SUPPORT TO AIR MONITORING OPERATIONS

S. HOCHHEISER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Consult with state and local agencies regarding analytical techniques and necessary laboratory support to air monitoring activities. perform routine sample analyses where such capability is not otherwise available in AQCR, instruct State and local personnel in operation, maintenance, and calibration of air monitoring instruments and in laboratory procedures for analysis of air pollution samples. The latter will be conducted in NAPCA facilities located in Durham and the Research Triangle.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0776, TECHNICAL SUPPORT TO FEDERAL FACILITIES - SOURCE SAMPLE ANALYSIS - AIR MONITORING - AND VEGETATION EFFECTS

S. HOCHHEISER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Review plans for establishing air monitoring networks. Provide guidance in selection, operation, maintenance, and calibration of air sampling instruments. Participates in source test conducted by the Engineering Branch and performs chemical analysis of source samples. Make field inspections to determine possible vegetation damage due to emissions from Federal facilities.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0777, MAINTAIN AND PROVIDE UP-TO-DATE INFORMATION ON AIR POLLUTANT EMISSION FACTORS

A. HOFFMAN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To continually collect all available source sampling data and establish new and update existing emission factors.

Approach: Through literature surveys and personal contact with internal and external organizations, collect all data on emission rates and develop emission factors.

Goal: Issue an addendum to the Emission Factor Book.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0778, DEVELOPMENT OF HEAVY HYDROCARBON ANALYZER AND EVALUATION OF CONTINUOUS OXIDES OF NITROGEN ANALYZER FOR ADVANCED POWER PLANT STUDIES

M.W. KORTH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Many of the advanced vehicle power plants being considered can burn heavier hydrocarbon fuels that produce a heavier molecular range of compounds in the combustion products. These hydrocarbons are difficult to sample and analyze and require the development of more suitable total hydrocarbon instrumentation for this purpose.

The more sensitive techniques for continuous measurement of oxides of nitrogen as required for advanced power plant studies will be evaluated.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0779, DEVELOPMENT OF IN-HOUSE INSTRUMENTAL METHODS

R.L. LARKIN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Continuing support as needed.

1. AIR QUALITY

Description: Investigate instrumental methods for application to in-house analytical problems. Apply automation to the needs of basic engineering studies and extend continuous measurement to other than present gaseous pollutants such as; C12, COCl2, HCL, HCN, etc. and instrument such analyses as; SO4 minus minus, NO2 minus, NO3 minus, SO3 minus minus, etc.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0780, PROVIDE TECHNICAL ASSISTANCE TO STATE AND LOCAL AGENCIES REGARDING SPECIAL AIR QUALITY SURVEILLANCE PROJECTS
R.E. LEE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To provide technical assistance to state and local agencies pertaining to unique and unusual surveillance problems of a non-routine nature.

Approach: By personal correspondence, either by telephone or written form, or by visits, guide non-federal agencies regarding surveillance projects. For example, requests in the past have been made concerning the construction of a low noise-level hi vol sampler for indoor use, and advice on determining the size distribution of hot iron oxide particles emanating from a smelting process.

Goal: Maintain contact with interested non-federal agencies and provide technical assistance where applicable.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0781, OPERATE A SPECIAL NETWORK FOR DETERMINING THE SIZE DISTRIBUTION OF PARTICULATES BY USE OF CASCADE IMPACTOR
R.E. LEE, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Determine the size distribution of particulates gravimetrically at selected locations in the nation and to quantitate their chemical composition.

Approach: A modified Andersen Cascade Impactor will be used to separate particulates into 5 fractions below 3 microns size. Mass particle size distributions will be determined by the NASNB while cation and anion species present in each fraction will be determined by the LSB.

Goal: In addition to the 6 cascade impactors now operating at CAMP cities, 5 additional impactors will be set up and operated at urban sites; all ll stations will be operated for a 24 hour period 26 times a year on the NASN schedule.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0782, MONITOR 1) CO-CH4 BY GC, 2) O3 BY CHEMILUMINESCENCE, 3) H2S BY ELECTROLYTIC DETECTORS, & 4) PARTICULATES BY SPOT EVALUATORS (ABBREV)
F. MCELROY, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Contingent upon successfully meeting all field testing requirements, add nes sensors, and improve capabilities of continuous monitoring stations. Data to be collected on pollutants not previously monitored will be used in preparation of criteria documents.

Approach: New instruments and samplers will be installed in CAMP stations. These instruments will provide new data which is urgently needed to support criteria documents.

Goal: After completing laboratory evaluation of CO-CH4, O3, H2S, and particulate devices, install in CAMP stations, and initiate long- term monitoring.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0783, OPERATE A NETWORK OF CONTINUOUS MONITORING RESEARCH STATIONS (CAMP)
F. MCELROY, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To operate continuous monitoring research stations for pollutant characterization, instrument development, demonstration projects, HAPP data.

Approach: Continue to operate CAMP with a research-oriented objective. On a long-term basis, obtain data for trend analysis, new pollutants, sensor development, criteria documents, and HAPP information.

Goal: Supply continuous data on pollutants emanating from industrial and automotive combustion processes. These will include SO2, NO2, CO, oxidants, methane, total hydrocarbons. CAMP stations will also be used as field testing sites for the evaluation of newly-developed monitoring devices for ozone, fluorides, lead, and H2S. On a limited basis use data to determine compliance with standards in AQCR's. Additional equipment to be used for accomplishment includes data-logger for back-up purposes.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0784, FIELD PERFORMANCE AND APPLICATION EVALUATION OF BARRINGER REMOTE SENSING AND INSTACK MEASUREMENT OF SO2 EMISSIONS BY CORRELATION SPECTROSCOPY
J.S. NADER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Barringer UV correlation instruments are being purchased for longpath/ remote and for instack measurement of SO2 emissions. A preliminary evaluation under contract study indicated favorable performance with limitations due to environmental conditions. A more detailed in-house study is planned in the field with independent simultaneous remote measurements using newly acquired field research instruments, Convair and Bendix Remote IR Scanning Spectrophotometers.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0785, EXPAND SAROAD TO SERVE THE NEEDS OF NADIS
G. NEHLS, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To shorten the potential access time to the data files in the National Aerometric Data BAnk and expand the types of routine summaries and computations available through SAROAD and make SAROAD compatible with State and local agency data requirements.

Approach: A redesign of SAROAD considering the needs and uses of information by other NAPCA components and State and local agencies will be undertaken. Concurrently, expansion of the existing system to include more summaries such as pollution roses and graphical presentation will be started. Transfer of SAROAD to a large third generation system will be initiated to take advantage of the increased capabilities and speed these machines offer.

Goal: Redesign SAROAD, initiate transfer to a third generation computer, increase the reports available through SAROAD.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0786, PERFORM INTERNATIONAL STUDIES IN SELECTED NATO COUNTRIES TO ASSESS ATMOSPHERIC POLLUTANT CONCENTRATIONS AND EMISSIONS
G. OZOLINS, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To procure data for predicting emissions to the year 2000, in selected NATO countries. Data will be used as primary input for the diffusion model being coordinated by the Office of Science and Technology.

Approach: By installing various samplers and monitoring stations at selected sites in the area to be studied, obtain continuous and integrated data which may be used to verify diffusion models developed from source information.

Goal: Perform an inter-divisional study in Ankara, Turkey to obtain SO2 and particulate concentrations at 10 selected locations within the city.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0787, SAMPLING OF SO2 CONCENTRATIONS AND RELATED METEOROLOGY
F. POOLER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Complete data acquisition for Keystone and Homer City Power Plants, by aircraft and ground sampling of SO2 concentrations and related meteorology. Small particle (nuclei) count and tracers in plumes may be used for assessing plume transport and dispersion.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0788, ANALYZE THE CYCLICAL VARIATION OF AIR QUALITY
J. REAGAN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To assess the underlying cyclical variation n air quality levels and develop standard curves for expected time fluctuations.

Approach: time series analysis along with auto-correlation can be used to estimate the major weekly and seasonal changes. More attention will be required to tease out a standard diurnal variation that is independent of weekly or seasonal characteristics. Moreover, the analysis will attempt to identify predictable cycles which are tied to events which occur randomly in time. Standard curves will be developed which can be used to remove known cyclical components and the resulting data would be similar to the adjusted economic indices.

Goal: Identify and quantify in standard curves the expected cyclical variation of particulates and sulfur dioxide.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0789, MEASUREMENT TECHNIQUES FOR THE NUCLEIC ACIDS AND THEIR BREAKDOWN PRODUCTS
E. SAWICKI, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

These methods are being assembled and developed. The first compound under investigation is 2-deoxyribose. Since some of the heterocyclic products are potent oncogens, methods for their analysis will be looked into. In the first phase, methods of analysis for 2- deoxyribose, a key component of DNA, are being assembled, preparatory to investigation of airborne particles in terms of these compounds.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0790, CONSOLIDATION & IMPROVEMENT OF ASSAY METHODS FOR THE CARCINOGEN FAMILY
E. SAWICKI, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Consolidation of the large number of methods which have been developed for the determination of the airborne carcinogen family. An attempt will be made to modify and improve the key methodology and then assemble it for future use in criteria documents.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0791, MEASUREMENT TECHNIQUES FOR PRE-ALLERGENS
E. SAWICKI, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Airborne dusts are known which, when fresh, are non-allergenic, and aged are allergenic. It is believed that a chemical reaction takes place in these dusts. Some evidence indicates that polyhydroxyaldehydes and peptides containing the lysine group may be implicated in one such reaction. First phase involves literature survey followed by organization and development of methods of assay for the appropriate components and then eventual application to various airborne dusts.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0792, ANALYSIS OF FLAVONOLS AND OTHER PHENOLS
E. SAWICKI, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

These colored compounds are prominent components of many types of airborne bioparticles. Phenols could serve as indicators of pollen pollution and also indicators of certain types of natural and man-made pollutions. Work is proceeding on measuring these compounds in various types of airborne particles.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0793, LIQUID CHROMATOGRAPHY STUDIES
E. SAWICKI, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Two types of investigations will be pursued. These include the feasibility of substituting this type of instrumentation for the column chromatographic techniques now used in assaying carcinogens and research on the use of this instrumentation in separating and assaying many of the biologically important chemicals present in the atmosphere.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0794, CONTACT MONITORING OF INSTRUMENTATION DEVELOPMENTS FOR MOBILE SOURCES
J. SIGSBY, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Develop and monitor contracts to provide practical instrumentation for the monitoring of combustion effluents. Aldehydes in general and formaldehyde are of immediate concern. A mass spectrometer has been developed and is being evaluated in the first instance and a further method for formaldehyde will be developed in the latter case.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0795, EVALUATION OF METHODS FOR DETERMINATION OF NITROGEN OXIDES IN AUTOMOTIVE EMISSIONS
J. SIGSBY, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

This project is in direct response to a request from the Office of Criteria and Standards. All currently available instrumental methods of measuring oxides of nitrogen will be utilized. These include direct opticals such as NDIR, NDUV, chemiluminescent, electrochemical, wet chemical and others if available.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0796, DEFINITION OF OXIDE OF NITROGEN STANDARD
J. SIGSBY, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

A standard method(s) must be promulgated for the measurement of the oxides of nitrogen. It is to be enforced in the 1973 regulations.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0797, STANDARDIZATION OF METHOD FOR PARTICULATE EMISSIONS FROM MOBILE SOURCES
J. SIGSBY, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The sampling technique and instrumentation for particulate emissions from vehicles will be subjected to standardization procedures.

1. AIR QUALITY

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0798, OPERATE PORTABLE AND MOBILE METEOROLOGICAL EQUIPMENT IN POTENTIAL EPISODE SITUATIONS
H.H. SLATER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Maintain, deploy, operate meteorological equipment to obtain auxiliary weather information during potential or actual air pollution episode conditions. Analyze data in field and transmit data to meteorologists serving air pollution control agencies and NAPCA's EOCC. Calibrate, refurbish and maintain equipment in constant state of readiness.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0799, PROVIDE METEOROLOGICAL SUPPORT TO EMERGENCY EPISODE PLANNING
H.H. SLATER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Develop background meteorological and topographic reference material for areas most susceptible to air pollution episodes. Serve on NAPCA-ESSA Environmental Meteorological Service Unit Advisory Committee. Review and test atmospheric models for assessing the effect of meteorological factors on air quality during episodic situations.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0800, DEVELOP IMPROVED METHODS OF CALCULATING AND ANALYZING SURVEY DATA
J. SMITH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To obtain better methods of collecting, compiling, and analyzing emission data obtained from metropolitan inventory surveys.

Approach: Information gathered during previous surveys is analyzed with respect to improving existing means for use of computer in calculating emissions, selection of point sources, determination of grid sizes and averaging times. This activity is accomplished independently and in liason with DA and DM.

Goal: Develop a method for estimating emissions on a shorter averaging time basis (daily and, if possible, hourly).

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0801, ANALYZE SAMPLES FOR SO2 AND NO2
R.J. THOMPSON, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To determine SO2 and NO2 content of ambient air.

Approach: SO2 and NO2 concentrations are determined by metering ambient air through appropriate absorbing reagents and returning the exposed solutions to the contractor's laboratory for analysis. LSB will verify results with control samples. The pollutant concentrations determined by the contractor will be furnished to the DAAB and the tabulations prepared by them will be verified.

Goal: To determine the SO2 and NO2 concentrations of ambient air from samples collected biweekly at 250 NASN stations during the first and second quarters of 1971.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0802, DEVELOP EPISODE AIR MONITORING CAPABILITY
D. TYLER, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The purpose of this task is to develop a nation-wide episode air monitoring capability. This capability will enable the EOCC to acquire AQ data at any location in the nation that is threatened by an air pollution episode. In some areas this will be the only available source of date; for other areas it will be used to supplement local data.

The development of this monitoring capability will include the evaluation and purchase of portable air monitoring equipment and the organization and training of field crews in the use of the equipment. The field crews will be on-call at all times to respond to any episode situation.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0803, INSTRUMENT DEVELOPMENT AND EVALUATION FOR PARTICULATES
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Development and evaluation of new types of monitoring instruments to measure particulates and the key physiologically harmful components of these mixtures.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0804, EVALUATION OF ADVANCED SPECTROSCOPIC TECHNIQUES
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

For the past five years, a variety of spectroscopic techniques have been developed which tend to improve resolution and sensitivity to the measurement of complex mixtures of organic and inorganic compounds.

Among these techniques are microwave, correlation, Fourier transform and second derivative spectroscopy. In addition, development of monochromatic light sources could lead to a new generation of spectrometers. This task will select one or more of the above approaches to develop a working spectrometer for the simultaneous measurement of several pollutants such as SO2, CO, HCHO, NO and NO2.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0805, DEVELOP TECHNIQUES FOR STORING CHEMICAL INFORMATION PROPORTIONAL TO 24-HOUR AVERAGE CONCENTRATIONS OF SO2 AND NOX
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

A substrate (e.g., PbO2) will be sought that will a) absorb SO2 and NOX from a metered air sample passed therethrough, and b) desorb each of these gases separately during programmed thermal (or other) regeneration. Suitable readout mechanism will be selected from available known laboratory or instrumental methods.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0806, DEVELOPMENT AND TESTING OF A FLAME PHOTOMETRIC DETECTOR DESIGNED TO MEASURE OXIDES OF NITROGEN
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

It is known that oxides of nitrogen produces an intense luminescence, proportional to concentration, in hydrogen rich flames. Studies are in progress to determine the applicability of photometric monitoring of this light to the real-time monitoring of NOx.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0807, FRABRICATION AND EVALUATION OF A PORTABLE FLAME PHOTOMETRIC DETECTOR DESIGNED TO MEASURE SO2 AND NOX IN STACK PLUMES
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

For the past two years we have evaluated the performance of the flame photometric detector as a monitor for ambient concentrations of SO2. This monitor has real time response, therefore would serve as an ideal measuring tool for determining plume dimensions and concentrations. Within this task a special portable, battery operated FPD will be fabricated and tested as a plume monitor for both SO2 and NOX.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0808, EVALUATION OF ELECTROCHEMICAL SENSORS FOR SOURCE CONCENTRATIONS OF SO2 AND NOX
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Several commercial devices are available to measure emissions from mobile and stationary sources. NAPCA has funded development of electrochemical sensors designed to measure SO2 and NOX. These sensors will be evaluated in conjunction with special accessory sample handling equipment under conditions simulating those encountered in stack sampling. Gas samples will be provided similar to the gases emanating from stacks to determine reliability and accuracy of these new sensors.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0809, ANALYTICAL METHODS EVALUATION SERVICE
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

The SAC in cooperation with the Intersociety Committee selects tentative methods for analysis of pollutants. AMES then evaluates the methods in the laboratory and conducts collaborative tests to determine bias and reproducibility. Following the study, the results are published. Collaborative testing of methods is necessary before adoption as standard methods, and air pollution control is dependent upon methods which have been found to have acceptable and known reproducibility. This is a continuing operation to provide established analytical methods for NAPCA use.

In conducting a collaborative testing program, as in CP-70-40, presently in progress; it is of primary importance that the laboratories selected be technically competent. Although competent, all of the laboratories may not be fully equipped to follow the method in every required detail. Therefore, it will be necessary to provide certain equipment on loan to these laboratories, as well as materials necessary to collaborative testing of the methods. These are: primary standard positive displacement meters, orifice calibration units, and filters for measurement of particulates. General items: flowmeters, standard thermometers, standard reagents (at least two for each ten methods) will also be required. Additionally, instruments for measuring hydrocarbons and CO, ozone generators, sources of CO and hydrocarbons (for calibration) will be needed.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0810, COMPLETE A REPORT ON INDOOR-OUTDOOR AIR QUALITY FOR SOX - TSP AND OTHER AIR POLLUTANTS
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Although ambient levels of air pollution in many of our major cities are quite high, only a small percentage of the citizenry spend a significant portion of their time outdoors and thus are exposed directly to it. It is imperative for this reason, that techniques be developed for determining the relationship between outdoor air pollution levels and those found within homes or other occupied situations. A study of this type relative to SO sub X and particulate levels will be completed during the current fiscal year.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0811, DEVELOP NOX MEASUREMENT PROCEDURE FOR FEDERAL REGISTER
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Based on evaluation of present NO sub x measurement methods, recommend procedures for subsequent publication in Federal Register.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0812, DEVELOP EMISSION RATES FOR MOBILE SOURCES
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Using certification, durability and surveillance data, determine periodically the emission rates for mobile sources relative to HC, CO, NOx, total particulates, lead, SOx and polycyclic organic matter.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0813, DETERMINE TIME-CONCENTRATION-FREQUENCY RELATIONSHIPS IN AQCR'S FOR SOX, PARTICULATES, NO, HC, CO AND OXIDANTS
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Conversion of raw aerometric data into a statistically useable form. This will permit existing air quality data to be related to the reference air quality standards established in the criteria documents.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0814, ANALYZE SAMPLES OBTAINED FROM THE COOPERATIVE STUDY CONDUCTED IN ENGLAND
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To analyze suspended particulate samples collected in the England smoke-shade-U.S. particulate study for selected pollutants.

Approach: Appropriate analytical methods will be used to analyze the samples for inorganic, organic and trace metals constituents.

Goal: To analyze the approximately 2000 samples collected in England for total suspended particulate. Some 220 selected samples will be analyzed for some 30 trace metals and non-metal inorganics. Some ten composites of the samples collected will be analyzed for benzene soluble organics and benzo(a)pyrene.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0815, OPERATE A SPECIAL NETWORK FOR THE COLLECTION OF ARSENIC AND SELENIUM
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Sample the ambient air to be able to determine the air quality for Hg and As. Information would be of use in publishing criteria documents and in prescribing standards.

Approach: By using gas bubblers collecting 24-hour air samples and by a mobile van utilizing a continuous analyzer.

Goal: Establish samplers at approximately 50 sites where large manufacturers or users of arsenials and selenium containing materials are located.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0816, OPERATE A NATIONAL NETWORK FOR SAMPLING GASEOUS POLLUTANTS AT AN INCREASED FREQUENCY
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Increase the sampling frequency to obtain a higher degree of statistical accuracy for the determination 24 hour averages and maximum values for the pollutants emitted into the atmosphere in major quantities.

Approach: Increase the sampling frequency of the present gas- bubbler sampler network to determine concentration levels of SO2, NO2, and at specific locations Hg, Cl2, HCl, etc.

Goal: Collect air samples for subsequent analysis for SO2, NO2, Hg, (not at all sites) and others at a frequency of 120 times per year at approximately 200 sites.

1. AIR QUALITY

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0817, ANALYZE COLLECTED PARTICULATE POLLUTANT FOR SOLUBLE NON-METAL IONS
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To determine the ammonium, fluoride, nitrate, and sulfate ion concentration of selected NASN samples.

Approach: Samples of particulate matter collected in glass-fiber filters are extracted with water and the ammonium, fluoride, nitrate and sulfate ion contents determined. The ambient air concentrations of these ions are calculated and tabulations of these data prepared by DAAB are verified.

Goal: To analyze some 3,000 selected samples collected in 1969 and 1970 for ammonium, fluoride, nitrate and sulfate ions and to calculate the ambient air concentration of these ions.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0818, DEVELOP A PROCEDURE FOR THE COLLECTION OF AND ANALYSIS FOR FILTERABLE ('ORGANIC') LEAD FROM AMBIENT AIR
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To develop a procedure for the collection of and analysis for filterable ('organic') lead from ambient air.

Approach: Appropriate absorbing reagents will be used to collect the lead from filtered ambient air and appropriate analytical methods will be used to determine the lead concentration of the exposed reagent. An evaluation of collection and analytical efficiency and of analytical precision will be made.

Goal: To develop and evaluate a method for the collection of and analysis for filterable ('organic') lead from ambient air.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0819, ESTABLISH THE EFFICIENCY OF RECOVERY OF BERYLLIUM FROM SAMPLES OF COLLECTED PARTICULATE MATTER
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To determine the efficiency of recovery of beryllium from particulate matter using LSB analytical procedure.

Approach: Beryllium compounds, including 'high-fired' beryllium oxide (a refractory substance which may defy chemical procedures amenable to routine analysis), thought to be in the atmosphere will be added as known spikes to samples of collected particulate pollutants and then subjected to our analytical procedure which is based on optical emission spectrometry. In this manner the efficiency of recovery can be determined.

Goal: To establish the efficiency of recovery of beryllium from samples of collected ambient air particulate matter.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0820, CONSULT WITH LOCAL, STATE, REGIONAL, AND OTHER FEDERAL AGENCIES ON ANALYTICAL METHODOLOGY AND PROCEDURES
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To consult with personnel of appropriate organizations internal and external to NAPCA on analytical methodology relative to measuring air pollution. This assures use and acceptance of NAPCA's methodologies.

Approach: Consultation on procedures and methodology by LSB personnel will be provided by conferences, phone conversations and by correspondence. A member of the LSB staff serves as member of the Standardization Advisory Committee and all professional staff members serve as consultants to the SAC as requested. Other consulting by LSB personnel includes lecturing at training courses and task force assignments.

Goal: To provide this service as requested when mutually agreed upon.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0821, ON-THE-JOB TRAINING FOR PERSONNEL OF REGIONAL, STATE, LOCAL AND OTHER FEDERAL AGENCIES OR OTHER NAPCA PROGRAMS (ABBREV)
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To assist personnel of appropriate outside organizations by providing on-the-job training to their chemists in the methods used within LSB to assure comparability of methodologies used and to assure quality control of the data engendered.

Approach: The chemist of the outside organization works in the Branch laboratory under the guidance and direction of branch personnel and in this manner learns in detail how methods used here operate and how he can best adapt them to his needs.

Goal: To provide this service when requested as mutually agreed upon.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0822, PROVIDE ANALYTICAL SERVICES TO REGIONAL, STATE, LOCAL & OTHER FEDERAL AGENCIES, TO OTHER NAPCA PROGRAMS & OTHER APPROPRIATE ORGANIZATIONS
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To analyze samples of air pollutants received from appropriate organizations outside DAQED; in order to assure comparability of data and to render technical assistance to state, local, and other federal agencies.

Approach: As the workload permits, LSB personnel, who have broad experience in analyzing for a wide variety of air pollutants, will use the methods within their capability to analyze air pollution samples received from outside organizations. Technical support to the Measurement Standardization Services Section of DCP will be provided. Participate in NAPCA's collaborative testing study program.

Goal: To provide these services when requested as mutually agreed upon.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0823, ANALYZE SAMPLES FOR SO2 AND NO2
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To determine SO2 and NO2 content of ambient air.

Approach: SO2 and NO2 concentrations are determined by metering ambient air through appropriate absorbing reagents and returning the exposed solutions to the contractor's laboratory for analysis. LSB will verify results with control samples. The pollutant concentrations determined by the contractor will be furnished to the DAAB and the tabulations prepared by them will be verified.

Goal: To determine the SO2 and NO2 concentrations of ambient air from samples collected every third day at 200 NASN stations during the first and second quarters of 1971.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0824, WEIGH AND COMPUTE CONCENTRATION OF SUSPENDED PARTICULATE MATTER IN SAMPLES COLLECTED BY THE NASN
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To prepare for field use glass-fiber and membrane filters and to compute total suspended particulate concentration and prepare for fractional analysis these filters after samples have been collected in the NASN.

Approach: Glass-fiber and membrane filters are screened, numbered, equilibrated with a controlled (temperature and humidity) atmosphere, weighed, packaged and furnished to th.

NASN for field use. The filters received from the NASN loaded with collected particulate matter are equilibrated, reweighed and divided for fractional analysis. The total suspended particulate concentration is calculated and tabulations of these data prepared by DAAB are verified.

Goal: To process for field use some 45,000 glass-fiber and 6,000 membrane filters and to reweigh, calculate total suspended particulate concentration and prepare for fractional analysis all particulate samples received from the NASN.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0825, ANALYZE COLLECTED SAMPLES OF SUSPENDED PARTICULATE MATTER FOR BENZENE SOLUBLE ORGANICS AND FOR BENZO(A)PYRENE

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To determine the benzene soluble fraction and benzo(a)pyrene concentrations of ambient air for evaluation of air quality.

Approach: Quarterly composites of portions of particulate matter collected on glass-fiber in the regular NASNO are extracted with benzene and the benzene soluble fraction (BSO) determined. The benzo(a)pyrene (BaP) is separated from the BSO by thin-layer chromatography and determined by spectrophotofluorescence. The ambient air concentrations of BSO and BaP are calculated and the tabulations of these data prepared by DAAB are verified.

Goal: To determine the BSO and BaP concentrations of ambient air from quarterly composites of samples of suspended particulate matter received from the regular NASN March 31, 1970 through March 31, 1971.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0826, FIELD INVESTIGATION IN A NEW ABATEMENT CASE

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Plan and conduct a field investigation designed to delineate the nature and extent of air pollution in the area. Employ survey technique and measurement procedures consistent with definition of the air pollution problem. Commit the necessary manpower and material resources in the area of pollution and effects monitoring. Prepare a pre- conference abatement report.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0827, AQCR ASSISTANCE - AIR QUALITY DATA

UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Assist the States in the design and operation of air monitor systems. Such assistance will include consultation on procedures for reducing and analyzing air quality data.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0828, AIR MONITORING INSTRUMENT LOAN AND CONSULTATION TO ESTABLISH DATA BASE IN AQAR'S

R.T. WALSH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Loan equipment to agencies on a short-term basis to establish existing air quality. Assistance will be provided in the selection of monitoring sites and the installation and calibration of instruments. In FY-71, emphasis will be placed on about 80 AQCR's for which initial plans are due from October '70 through December '71. The instruments will be used to measure concentrations of sulfur oxides, particulates, oxidants, hydro-carbons, carbon monoxide, and nitrogen oxides.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0829, ANALYSIS OF LIPIDS IN AEROBIOLOGICAL PARTICLES

E. WITTGENSTEIN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Development of methods of assay for aerolipids. These would include steroids, esters, and many other ether-soluble compounds. Urban particles would also be analyzed for these materials.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0830, DEVELOPMENT OF AIR SAMPLING METHODOLOGY

B.E. SALTZMAN, Univ. of Cincinnati, School of Medicine, *Cincinnati, Ohio* 45221

The objectives of this study are to examine critically and improve the present technology for air sampling and analysis. More sensitive and specific analytical methods are being sought in order to make possible accurate measurements of low levels of pollutants. Improved and simplified means for calibrating, standardizing and automating these system are sought.

The work for the current year will be conducted in the followed areas: a) Monitoring systems for determining reactive hydrocarbons in the air by use of absorbent chemicals for removing classes of compounds. b) Stoichiometry of nitrogen dioxide analytical methods and use of solid absorbents for sampling. c) Sampling of gases with chemically impregnated filters. d) Sampling of aerosols with size selective samplers.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0831, ANALYZE SAMPLES COLLECTED FROM AMBIENT AIR FOR TOTAL MERCURY

W. HENRY, Battelle Memorial Institute, *Columbus, Ohio* 43201

Objective: To determine total mercury content of ambient air.

Approach: Total atmospheric mercury concentrations are determined by metering ambient air through an absorbing reagent and delivering the exposed solutions to the contractor for analysis. Deliveries will be made once per quarter. LSB will verify results with control samples. The pollutant concentrations determined by the contractor will be furnished to the DAAB and the tabulations prepared by them will be verified.

Goal: To determine the total mercury concentration of ambient air from approximately 1,000 samples collected biweekly at 60 NASN sites through March 31, 1971.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0832, ANALYSIS OF SUSPENDED PARTICULATE SAMPLES (ABBREV)

W. HENRY, Battelle Memorial Institute, *Columbus, Ohio* 43201

Objective: To determine the elemental composition of collected suspended particulate matter and to determine the ions, molecules and compounds present in high enough concentration for their measurement.

Approach: The following analytical techniques will be used to make the above determinations: classical wet chemistry, X-ray crystallography, microscopy, microprobe analysis, emission, flame and atomic absorption spectrophotometry, spark-source mass spectrometry, etc. Virtually every tool available to the analytical chemist will be utilized.

Goal: To determine the elemental composition and to determine the ions, molecules and compounds present in high enough concentration in some 25 samples of collected suspended particulate matter.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0833, IMPROVE AND QUANTITATE A TENTATIVE METHOD FOR ASBESTOS

W. HENRY, Battelle Memorial Institute, *Columbus, Ohio* 43201

Objective: To improve and quantitate a tentative method for asbestos developed previously and to evaluate the improved method using field samples.

Approach: The routine method developed for the analysis of asbestos in collected particulate samples will be quantitated using chamber studies and will be improved by appropriate modification. The improved method will be proven by use on samples collected at source and background sites by NAPCA.

1. AIR QUALITY

Goal: To improve and quantitate the tentative method for asbestos and to prove the improved method using field samples.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0834, DEVELOPMENT OF A WORKING MODEL FOR MEASUREMENT OF SULFUR DIOXIDE IN STACK GASES
R. PHEIFER, Industrial Nucleonics Corp., *Columbus, Ohio* 43202 (AT(30-1)-3882)

Despite the emergence of nuclear energy as a major source of energy for industrial and commerical use, utilization of fossil fuels will increase significantly in the future due to numerous economic advantages of fossil fuels in many localities. However, federal and local regulations will soon become widespread concerning the control of air pollution, particularly sulfur dioxide pollution, resulting from the burning of fossil fuels. In conjunction with such regulations, adequate monitoring of smokestack emissions may become necessary for control and regulation compliance functions. Since no sulfur dioxide measuring instrument currently available meets requirements of low cost, high reliability, and easy maintainability over long periods of time, the Atomic Energy Commission has embarked upon a program to develop a suitable monitor.

The program is currently in its second year. Initial effort was spent on a study of the feasible techniques for monitoring the sulfur dioxide. Recent effort has been devoted to the development of a working model of the most promising monitoring method, the mercury substitution- nucleonic detection method. Currently, this program is in a field testing phase. Contingent on satisfactory performance of the working model in the testing, further effort will be expended on the development of a prototype instrument.

The instrument currently being developed is based on a mercury substitution-nucleonic detection principle. In the reaction cell of the instrument, sulfur dioxide reacts with solid mercurous chloride in a buffered aqueous medium to produce a soluble mercury complex, the bis- sulfitomercurate ion. This complex flows through a filter and passes into a measurement cell where the transmission of low energy cadmium-109 X-rays (22 kev) is measured with a scintillator-multiplier phototube combination and digital electronics.

Maintenance-free operation has been provided for periods of several days; the design goal of performance is one to two weeks. Maintainability of the instrument is easy; the disposable reaction cell with a charge of mercurous chloride is changed at weekly intervals. Due to the wet chemical measurement technique, the gas sample need not be cleaned or dried prior to analysis. Future development work will depend on the total results of the testing program.

SUPPORTED BY U.S. Atomic Energy Commission

1.0835, MICROANALYTICAL METHODS FOR AIR FORCE MATERIALS IN TOXICOLOGICAL AND ENVIRONMENTAL POLLUTION INVESTIGATION
E.L. ARNOLD, U.S. Air Force, Aerospace Med. Res. Lab. 6570, *Dayton, Ohio* 45433

Toxicological and environmental pollution investigation requires microanalytical methods for the materials of interest and for substances that are involved in the biological response. This work unit is directed to the development of rapid analytical techniques for halogenated derivatives of beryllium and catecholamines in biological and environmental samples and will provide the Air Force with sensitive methods for studies of beryllium propellant toxicity and potential pollution attendant with beryllium propellant testing and use.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0836, SINGLE COMBUSTOR RIG INVESTIGATION OF TURBINE ENGINE EXHAUST EMISSIONS
D. CHAMPAGNE, U.S. Air Force, Aerospace Propulsion Lab., *Dayton, Ohio*

Technical Objective: Upgrade and use the existing T56 engine single combustor rig as a readily available testbed to investigate phenomena related to turbine engine exhaust (mass) emissions, such as: determining the characteristics (response times, specificity, etc.) of some state-of-the-art exhaust species measurement instrumentation and evaluating fuel additives proposed for exhaust emissions control.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0837, THE CLIMATOLOGICAL BASIS FOR MANAGEMENT OF OREGON'S AIR RESOURCES
W.P. LOWRY, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00814)

OBJECTIVE: Develop methods of identifying periods of time when atmospheric conditions are conducive to poor air quality conditions and to good air quality conditions in the major airsheds of Oregon. Employ existing weather records in describing time and space patterns of occurrence of conditions in Oregon as identified by the methods developed under Objective 1.

APPROACH: Climatological and air quality data will be assembled from all regions of Oregon. Studies will then be carried out to identify those combinations of weather variables most consistently linked with known occurrences of very poor and very good air quality, taking into account information on forest slash burning, field burning, and domestic heating.

PROGRESS: Devised and reported on an index number to be calculated each day from radiosonde temperature values and from visibility values obtained at Weather Bureau stations, the number to be used as a guide in decisions whether or not to permit open burning, or other air pollution control measures. Also, obtained field data with which to assess the utility of the ratio (Flux of diffuse shortwave radiation/Flux of direct shortwave radiation) as an indicator of total particulate loading in the atmospheric column between the radiometer and the sun.

SUPPORTED BY Oregon State Government

1.0838, DEVELOPMENT OF A MULTICOMPONENT DEVICE FOR 24-HOUR CUMULATIVE MEASUREMENTS OF SO2 AND NOX
R. CHAND, Dynasciences Corporation, *Blue Bell, Pennsylvania* 19422

For the past year the Division of Chemistry and Physics has supported research to develop electrochemical sensors capable of measuring source concentrations of SO sub 2 and NO sub x. An extension of this work will be the fabrication of an inexpensive multicomponent analyzer which measures ambient concentrations of SO sub 2 and NO sub x and accumulates an electrical signal in proportion thereto.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0839, IMPLEMENTATION OF A LASER AS AN AIR POLLUTION PROBE
F. MEZGER, State Div. of Air Pol. Control, *Harrisburg, Pennsylvania*

Objectives and Procedures: The purpose of the study is to develop, build, test, and evaluate--both technically and economically--the effectiveness of a laser as an air pollution probe from a single point for a large area. The technique has only had laboratory testing, and this would be the first filed application for a new type of air pollution monitoring program. It is hoped that the costs of the laser technique will be significantly less than methods now employed and would provide better and more continuous data.

SUPPORTED BY U.S. Dept. of Commerce - Econ. Dev. Admin.

1.0840, ASTM SUBCOMMITTEE ON SENSORY METHODS OF MEASUREMENT
UNKNOWN, Amer. Soc. for Testing Mat., *Philadelphia, Pennsylvania* 19103

Participate in joint activities with industry and other government representatives on methods for classifying air pollutants from mobile systems in terms of sensory effects to human subjects.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0841, IMPLEMENTATION OF A LASER AS AN AIR POLLUTION PROBE
UNKNOWN, Drexel University, Graduate School, *Philadelphia, Pennsylvania* 19140

No summary has been provided to the Science Information Exchange.

SUPPORTED BY U.S. Dept. of Commerce - Econ. Dev. Admin.

1.0842, AIR POLLUTION FROM MINING, PROCESSING, AND UTILIZATION OF MINERALS AND FUELS
W.P. HAYNES, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

To develop the expertise needed to efficiently apply remote sensing techniques to environmental program. Specific goals are to determine feasibility of correlating SO2 and NO sub X concentrations with photographically detectable effects on vegetation and to ascertain the capabilities of multispectral scanning techniques for atmospheric monitoring.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0843, DEVELOP & IMPLEMENT OPERATIONAL SYSTEM FOR EVALUATING & COLLABORATIVELY TESTING METHODS RECOMMENDED FOR AIR POLLUTION MEASUREMENT (ABBREV)
H.C. MCKEE, Southwest Research Institute, *Houston, Texas* 77006

Develop a system for evaluating and collaboratively testing methods recommended for air pollution measurements. The contractor shall develop the system and then prove the system by evaluating and conducting collaborative tests for 20 methods recommended by the Standardization Advisory Committee of NAPCA and the Intersociety Committee of the Private Sector. Pollutants, or classes, will include suspended particulates, sulfur dioxide, carbon monoxide, oxidants (ozone), methane and total hydrocarbons, carcinogens (Benzo (a)pyrene, etc.), aliphatic aldehydes, nitrogen dioxide, lead, and fluorides.

Priorities will be established by the present and/or anticipated issuance of Air Quality Criteria Documents and publication of Standards in the Federal Register.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0844, FIELD EVALUATION OF METHODS RECOMMENDED FOR COLLABORATIVE TESTING AND ADOPTION AS STANDARDS FOR AIR POLLUTION MEASUREMENTS
H.C. MCKEE, Southwest Research Institute, *Houston, Texas* 77006

Tentative methods, as approved by SAC, for 10 air pollutants will be evaluated under field conditions (mobile trailer) prior to subjecting the methods to collaborative testing. This dynamic evaluation of methods in ambient air prior to and/or concurrent with testing will allow the collaborative testing program (Contract No. CPA 70-40) to be much more meaningful and provide quantitative data under actual field operating conditions which can be used to determine utility and future requirements. Guidelines will be established by the SAC and its subcommittees responsible for technical review and revision of methods. Priorities, in terms of methods to be tested, will be established by the present and/or anticipated issuance of Air Quality Criteria Documents and Publication of Standards in the Federal Register.

1.0845, MEASUREMENT OF AIR AND WATER QUALITY
H.C. MCKEE, Southwest Research Institute, *Houston, Texas* 77006

No summary has been provided to the Science Information Exchange.

SUPPORTED BY No Formal Support Reported

1.0846, POLLUTANTS IN CHIMNEY STACK PLUMES
H.W. PRENGLE, Univ. of Houston, School of Engineering, *Houston, Texas* 77004

This is part of a 3-year program; the overall objective is to determine pollutants by remotely sensing the infrared emission signals from individual chemical species in hot gas plumes.

Specific objectives for the third year are: 1) Complete the assembly of the equipment system, and laboratory calibrate and test. 2) Start field measurements. 3) Extend and refine system and evaluate field measurements.

1.0847, IONIZATION METHODS OF GAS ANALYSIS
A. ZLATKIS, Univ. of Houston, Graduate School, *Houston, Texas* 77004

The purpose of this research will be to study and develop existing and new ionization detectors bearing in mind their application to atmospheric contamination problems. In particular, the research will be concentrated on the further development of the photoionization detector, micro cross section detector and helium ionization detector. The use of ultrapure helium as the discharge gas in the photoionization detector should make it responsive to all organic and inorganic gases and vapors. Further, air will be used as the carrier gas. The helium ionization and micro cross section detectors will also be used with ultrapure helium to effect sensitivity increases. In addition, a concentrating device (gas transmodulator) which will remove most of the carrier gas just prior to the detector, will be used to make these concentration sensitive detectors operate at their maxima.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0848, DEVELOPMENT OF ANALYTICAL TECHNIQUES FOR THE MEASUREMENT OF TRACE CONTAMINANTS IN AIR FORCE MANNED WEAPON SYSTEMS
K.G. IKELS, U.S. Air Force, School of Aerospace Med., *San Antonio, Texas* 78235

Technical Objective: This effort will provide technics and instrumentation for the detection of atmospheric contaminants in Air Force operational environments. In current aircraft using lox convertors, contamination of oxygen is a recurring problem with excessive time delay between suspected contamination and actual proof. Additionally, in closed or semi-closed cycle breathing systems, the accumulation of gaseous contaminants produced by men and equipment compounds the problem. The objective of this effort to develop analytical technics to quantitate in a reliable and technically simple manner, the gaseous contaminants present in the breathing atmosphere. This effort supports ATC surgeon's requirement for a rapid means of measuring lox contaminants.

1.0850, ATMOSPHERIC POLLUTION BY DIESEL ENGINES
R.A. FOSBERRY, Motor Indus. Res. Assoc., *Warwickshire, England, United Kingdom* (005078)

Methods of measuring diesel exhaust smoke are being studied. Investigations were carried out to determine (1) the relation

between subjective assessments of diesel exhaust smoke and objective measurements, and (2) the correlation between exhaust-smoke measurements made by different types of smokemeters. Results from the first part of the work show that the smoke levels at which observers object depend on both density and volume of smoke. They are higher for small engines than for larger ones and are lower for light colored than for dark colored vehicles. In the second part of the work, correlation was established between readings obtained with two commercially available smokemeters. Smoke readings obtained under steady-speed conditions are compared with readings obtained from free-acceleration and controlled acceleration tests on vehicles.

Document provided to SIE by the Highway Research Information Service.

1.0851, AIR POLLUTION SENSING

C.H. NELSON, U.S. Natl. Aero. & Space Adm., Langley Research Center, *Hampton, Virginia* 23365

The objective of this work is to develop techniques and systems for the remote detection and measurement of atmospheric pollutants from aircraft and orbital spacecraft. A nondispersive radiometric sensor for use in aircraft is being developed to verify a promising sensing technique for carbon monoxide, and will be expanded for flight measurements of other gaseous atmospheric pollutants. Ground measurements of the spectral characteristics of highly polluted urban atmospheres are being obtained from a mobile van containing an infrared monochrometer which views the sun's spectrum through a long atmospheric path. The development of instrumentation and technology on this RTOP will provide the basic design information for satellite systems or monitor air pollution levels and provide data on temporal and spatial distributions of pollutants wich are needed to allow development of analytical models to predict pollution levels and establish pollution controls. The investigator shown above is the Project Monitor whose telephone is 703-827-3825.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

1.0852, DETECTION OF SMALL AMOUNTS OF SO2 IN ATMOSPHERE

J. BECHER, Old Dominion University, Graduate School, *Norfolk, Virginia* 23508

A study to determine the feasibility of detecting pollutants in a controlled atmosphere is proposed. The method to determine the species and quantity of pollutants consists of condensing the pollutants onto a cooled total internal reflection crystal. Data are then obtained from the absorption spectra. A method relying on condensating small quantities of gases in multicomponent mixtures has been reported by Rochking.

Since the absorption coefficients of many of the gaseous pollutants ore large in the middle UV region (1200 Å degrees - 3000A degrees) of the spectrum, we propose to direct our investigations into that area.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0853, NAVY ENVIRONMENT SUITABILITY OF SALIVA SAMPLING FOR MONITORING BLOOD LEVELS OF INHALED POISONS AND OF ADMINISTERED MEDICATION

J.F. BORZELLECA, Virginia Commonwealth Univ., School of Medicine, *Richmond, Virginia* 23219 (N00014-68-A-0510-0001)

Technical Objective: The monitoring of blood concentrations of various materials, particularly toxic substances in the atmosphere, medication used to control or prevent disease and disability, and metabolic products which can serve as indices to fitness for duty, becomes a special Naval problem in many situations imposed by advancing Naval technology. In particular, the drawing of blood samples at intervals is difficult or impossible in closed, isolated quarters such as undersea habitats. Saliva offers promise of yielding the same information without need for skilled technical assistance in collecting samples, and without debilitating effects on the monitored individual. It is the purpose of this research to establish the knowledge needed to make such medical management feasible and reliable.

SUPPORTED BY U.S. Dept. of Defense - Navy

1.0854, EVALUATION OF A NEW 'CRYOGENIC SAMPLER' FOR FIELD USE

R.A. RASMUSSEN, Washington State University, School of Engineering, *Pullman, Washington* 99163

The major objective of the proposed investigation is to evaluate quantitatively a new environmental sampler, concentrator, and sample storage system for trace organics. The emphasis of the study is to refine the field use procedures to obtain maximum field utility and collection precision within the design criteria. The weakness of present cryogenic freeze-out systems in use in the laboratory is their restricted field utility and performance. The sampler developed is a compact, portable, self-powered unit for remote area operation, constructed of electropolished stainless steel and cleaned of organics in a high vacuum at 400 degrees C. The sampler is easily operated, has a high intake volume controlled by a critical orifice with a repeatibility of plus or minus 2%. Operation is very dependable and simple, with no frost-clogged lines, and has a first stage enrichment factor of 1000 fold. The development of a usable field collection system for trace organics would be a major asset in the study of the composition of natural clean atmospheres and polluted atmospheres.

1.0855, ATMOSPHERIC BOUNDARY LAYER TURBULENCE

T.W. HORST, Battelle Memorial Institute, *Richland, Washington* 99352 (AT)

The structure and dynamics of atmospheric turbulence and organized convective motions in the planetary boundary layer are being studied with the goal of prediction turbulence levels and parameterizing their role in the horizontal diffusion and vertical transport of atmospheric contaminates as a function of mean meteorological conditions. Experimental measurements utilize fast-response instrumentation mounted on towers, buoys, and aircraft for the simultaneous measurement of turbulent fluctuations of wind velocity, temperature, and humidity over both land and water surfaces. The mean meteorological conditions and their changes with time are simultaneously recorded with additional instrumentation. Various statistics and spectral distributions of these measured quantities and their auto- and cross-correlations are computed and studied along with the actual turbulence records in order to determine, as a function of height and thermal stability, the relative magnitudes of the several terms in the turbulent energy budget and the variation of the vertical fluxes of momentum, heat, and moisture.

Results: Turbulent fluctuations of temperature and wind were measured simultaneously at heights of 4 m, 16 m, and 58 m along with mean vertical profiles of temperature and wind. Steps necessary for the derivation of the surface Reynolds stress from cup anemometer wind profiles measured over nonideal terrain have been outlined and the vertical gradient of momentum transport resulting from the synoptic scale horizontal pressure gradient has been demonstrated. Turbulence data were also collected from the Florida State University's TRITON buoy as part of the BNW participation in BOMEX and reduction of this data begun.

SUPPORTED BY U.S. Atomic Energy Commission

1.0856, INFLUENCE OF AEROSOL CHARACTERISTICS ON VISIBILITY

R.J. CHARLSON, Univ. of Washington, School of Engineering, *Seattle, Washington* 98105

We propose to continue this research project, concerned with the effects of atmospheric aerosols and their properties on visibility, by investigating several directly related areas. Activities to date include the development of the integrating nephelometer, and studies with it related to mass concentration, wavelength dependence of light scattering, spatial distribution of aerosol and humidity dependence of visibility. Since this last area has only

been examined briefly, and because it depends on a better knowledge of aerosol chemistry, it will be studied much more extensively.

The role of the chemical composition of aerosols to their physical and optical response to increased humidity remains as an important and relatively unexplored problem. Preliminary work has shown that the nephelometer can be used for in situ studies at humidities approaching 100%. Field experiments at the sea-shore and at Pasadena have shown interesting but, as yet, unexplained effects at high (70-90%) and low (20-40%) RH respectively. The main thrust of the proposed renewal will be to examine the interrelationships of the three basic variables: 1) the amount, composition and size distribution of particulate matter, 2) humidity, 3) optical properties. In order to do this, it will be necessary to develop techniques for determining the necessary chemical properties. It is also desirable to continue to study methods for evaluation of the appropriate optical quantities. Extensive field experiments are envisaged in keeping with our approach in the past, including joint experiments with the Whitby team.

The past three years of research have had practical significance based on both scientific and technical results. An integrating nephelometer based on our drawings is being manufactured and used widely in both research and monitoring of visibility degradation. Perhaps more significance should be attached to the use of the (mass).(visual range) product as the basis of Chapter 3 of 'Air Quality Criteria for Particulate Matter.' The proposed research should have the same sort of significance. Specifically, criteria relating mass concentration and visibility as a function of composition and humidity can be anticipated.

1.0857, NUCLEAR METHODS OF ANALYSIS
R.F. STEWART, U.S. Dept. of the Interior, Bureau of Mines, *Morgantown, West Virginia*

Purpose: Continue development of nuclear methods of analysis for process control in the coal industry; tests of a neutron moisture meter have been completed and emphasis will be placed on testing a sulfur meter for coal.

Development of a continuous sulfur meter for coal is needed because of the national interest in air pollution from coal burning and because of the steel industry's emphasis on low-sulfur metallurgical coal.

A nuclear method has been developed for monitoring sulfur in coal samples as large as 4,000 pounds. Confirming tests with high sulfur oils and water solution indicate a sensitivity better than 0.05 percent sulfur. However, tests with moving coals are required to solve problems in material handling and bulk density changes. A coal recycle pilot plant has been completed for further testing of a sulfur meter. Initial operation demonstrated the need for lined buckets and density compensation and further tests are planned on completion of equipment modification.

The project was started in fiscal year 1961. A neutron moisture meter was completed in fiscal year 1969. Testing of a relatively slow sulfur meter will be completed in fiscal year 1970 and development of a fast sulfur meter in fiscal year 1971.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

1.0858, AN INTEGRATED SYSTEM FOR SAMPLING STACK EMISSIONS
R.F. STEWART, U.S. Dept. of the Interior, Bureau of Mines, *Morgantown, West Virginia*

This is a packaged system capable of automatic, continuous, and unattended operation for (1) sampling stack gases, (2) recording the concentration and size of particles in the gases, and (3) recording the various types and amounts of gases.

Work in F.Y. 1971 will be to continue the development of the EGD dust moniter in the laboratory. Work in the three previous fiscal years has shown that EGD can be applied to the simultaneous determination of the mass flow of dust and particle size in a gas stream. Work in F.Y 1971 will be with air as the carrier gas through the EGD channel and with the simultaneous feeding of two or more size fractions of fly ash in the air. Factorial experiments are employed in these tests to relate the variables to current outputs from the EGD monitor. If this work can be completed in F.Y. 1971, the next step will be similar tests in the laboratory using stack gas instead of air. The final step would be field tests of the EGD unit and the isokinetic sampling package.

1.0859, SATELLITE PLATFORM
V.E. SOUMI, Univ. of Wisconsin, Graduate School, *Madison, Wisconsin*

Demonstrate the feasibility of measuring total atmospheric pollution by measuring electromagnetic transmittance through the atmospheric limb, by indirect sensing techniques, using ground and co- orbiting satellite-borne electromagnetic energy receivers and sources.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0860, SURVEILLANCE - LOW TEMPERATURE PROPERTIES OF ELECTRONIC MATERIALS FOR DETECTION DEVICES
C. TERRY, Univ. of Wyoming, School of Arts, *Laramie, Wyoming* 82070 (N00014-71-C-0388)

Technical Objective: The work performed at low temperatures will characterize the behavior of prototype materials and assess suitability of certain physical effects which have technological importance for surveillance and communications. Effects in materials finding application in infrared systems, low loss radar waveguides, thermoelectric devices, and fast response detectors are studied down to 0.003 K.

SUPPORTED BY U.S. Dept. of Defense - Navy

H. BASIC RESEARCH

Basic Chemical and Physical Properties of Pollutants. Theoretical And Laboratory Studies Concerned With Air Pollution Formation, Identity, and Effects.

1.0861, HETEOGENEOUS REACTIONS IN AIR POLLUTION
G.D. BLYHOLDER, Univ. of Arkansas, Graduate School, *Fayetteville, Arkansas* 72701

It is the overall objective of this project to determine the role of particulate matter in chemical reactions occurring in the atmosphere. In the coming year we hope to: 1. determine the mechanism of the moderate temperature photochemical oxidation of CO by O2 on ZnO. 2. get started examining the photocatalytic and thermal catalytic oxidation of hydrocarbons on ZnO. 3. establish the structure of the species produced by NO2 on iron oxide and the products of reaction of these species with propylene and isopropanol. 4. establish the nature of the interaction of SO2 with iron oxide and the products of the reactions of alcohols and unsaturated hydrocarbons over iron oxide. 5. determine adsorption properties and reactions of atmospherically important molecules with CaSO4 as a start to examining the role of salts in the atmosphere.

1.0862, PHOTOCHEMISTRY OF SUBSTANCES PRESENT IN URBAN AIR
H.S. JOHNSON, Univ. of California, Graduate School, *Berkeley, California* 94720

In an effort to identify the organic peroxyl (or other) radicals that rapidly convert NO to NO2 in photochemical smog, we have studied the kinetics of the formaton of nitrous acid vapor, HNO2, from H2O, NO, and NO2; and we have studied the spectra and kinetics of the HOO and ClOO free radicals. Further work is in progress where we specifically look for CH3OO and CH3(CO)OO free radicals and where we scan the spectrum of the mixture NO2, O2, and simple olefins to see what free radical or other fast intermediates are present. Also, we are seeking to effect a substantial improvement in the performance of our new 'molecular modulation' methods.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0863, CATALYTIC REDUCTION OF OXIDES OF NITROGEN
E.E. PETERSEN, Univ. of California, School of Engineering, *Berkeley, California* 94720

Work on the catalytic reduction of nitric oxide by carbon monoxide will be continued during the next grant year.

Studies of nitric oxide reduction with carbon monoxide over a copper chromite catalyst have shown that at low temperatures or high space velocities N2O is formed as a final product rather than N2. During the next project period it is proposed to examine this phenomenon as it relates to fundamental phenomena occurring at the catalyst surface. For this purpose infrared absorption will be used to identify the form of the adsorbed reactants and the nature of the reaction intermediates on the catalyst surface.

A second area which will be examined is the relation of catalyst oxidation or reduction to its activity for the NO-CO reaction. In this study a single pellet reactor will be used. In addition to examining the effects of operating with reactant mixtures which are overall oxidizing or reducing, it is proposed to study the effects of small amounts of oxygen on the ability of the catalyst to reduce NO.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0864, PHOTOLYTIC OXIDATION IN THE PRESENCE OF NO2
S. JAFFE, Calif. State College, School of Letters, *Los Angeles, California* 90032

The photolytic oxidation of olefins in the presence of NO2 is under study in this laboratory. It has been found that simple epoxides, aldehydes and ketones are among the products of the reactions of oxygen atoms with olefins. We have recently investigated the reactions of propionaldehyde and ethylene oxide in the presence of NO2 and light with the objective of determining mechanisms and rate constants that would indicate that these secondary reactions are of importance in the photochemistry of air pollution. The objective of the proposed work is to investigate the reactions of acetone, propylene oxide, methyl ethyl ketone and butyl aldehydes in the presence of NO2 and light to extend our knowledge of the effect of these compounds on the total process.

In addition, butenes will be irradiated in the presence of NO2 and varying quantities of O2 to determine the effect of molecular oxygen on the process. Earlier work has indicated that as the O2 pressure is increased, the competition for O atoms by O2 to form ozone is important. The subsequent oxidation rate of the olefin is then reduced since the oxidation rate with O2 is slower than that with O atoms.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0865, POLARIZATION OF E.M. RADIATION IN A POLLUTED ATMOSPHERE
Z. SEKERA, Univ. of California, Graduate School, *Los Angeles, California* 90024

The proper evaluation of the relative importance of the various photo-chemical processes which occur in a polluted atmosphere is greatly facilitated by an understanding of the physical laws governing the interaction of the incoming radiation with the pollutant. It has been well established that the polarization features of the ambient radiation field exhibit a very sensitive dependence on these physical laws. Hence it is proposed to make multicolor measurements of the polarization features of the ambient radiation field in the near ultraviolet and visible regions of the spectrum from aboard a helicopter at various levels in and outside the pollutant layer over the Los Angeles basin. The results of these measurements will be of relevance in estimating how pollutant layers with different profiles define the resultant radiation field. Such an estimation is possible since theoretical solutions to the problem of radiative transfer in a turbid atmosphere are available.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0866, CATALYSTS FOR AUTOXIDATION OF TOXIC GASES
J.P. COLLMAN, Stanford University, Graduate School, *Palo Alto, California* 94305

Sulfur dioxide has been found to react with oxygen in the coordination sphere of transition-metal compounds to form coordinated sulfate. Similar reactions occur between carbon monoxide and oxygen to yield carbonate. Transition-metal clusters have been shown to be active catalysts when nitric oxide is present as a ligand.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0867, CONDENSATION NUCLEI AND AEROSOL POPULATIONS RELATED TO FOG FORMATION
E. ROBINSON, Stanford University, Graduate School, *Palo Alto, California* 94305 (DAHC04)

To determine the origins of sulfur compounds found in Pacific maritime aerosols and their relation to condensation processes, discover whether chloride ions are removed from fog droplets by reactions proposed by Robbins (1959) and whether removal depends on droplet size, and determine the effects of mixed populations of condensation nuclei on cloud condensation processes. Fog is one of the most important atmospheric conditions affecting Army operations. It influences military functions as detection and communications and directly affects the mobility of ground troops, and especially Army air operations. This project aims at increased knowledge about the initial stages of fog formation through a field study in a section of California where fog is being frequently formed to the west of the coast.

SUPPORTED BY U.S. Dept. of Defense - Army

1.0868, CHEMICAL AND SPECTROSCOPIC INVESTIGATION OF AIR POLLUTANTS
D.P. BURCHAM, U.S. Natl. Aero. & Space Adm., Jet Propulsion Laboratory, *Pasadena, California*

To contribute to the elimination of air pollution by investigating the chemical processes occurring in air pollution using the techniques of photochemistry and spectroscopy. Chemical studies will focus primarily on the photochemical production of air pollutants. Information from these studies is necessary in order to formulate realistic models of the chemical interactions occurring in the pollution process and to provide a meaningful basis for the establisment of acceptable pollutant concentrations in the atmosphere and in emission sources. studies by providing information of the detection, identification, and measurement of abundance and variation of pollutant molecules or radicals in the atmosphere. This part of the program utilizes the existing facilities for high resolution UV, visible and infrared spectroscopy at the Jet Propulsion Laboratory. This research can lead to effective control of pollutants by understanding their origin and production. The investigator shown above is the Project Monitor whose telephone is 213-354-3028.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

1.0869, MECHANISMS OF PHOTOCHEMICAL REACTIONS IN URBAN AIR
J.N. PITTS, Univ. of California, School of Letters, *Riverside, California* 95606

Reactions of possible importance in photochemical air pollution are being investigated. Photochemical studies include: (1) reactions of lead halides, both as finely dispersed particles and in aerosols, with other atmospheric pollutants such as ethylene, etc., and (2) reactions involving olefins and aromatics in the presence of oxygen, systems which are photochemically active due to oxygen-enhanced absorption which allows light in the actinic region (lambda greater than 300 nm) to be absorbed. Studies of the thermal (dark) chemistry of the reactive 'high energy' products of photochemical smog, ozone, nitrogen dioxide and peroxyacyl nitrates, are in progress.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0870, SINGLET MOLECULAR OXYGEN - OXIDATION IN POLLUTED AIR
J.N. PITTS, Univ. of California, School of Letters, *Riverside, California* 95606

Research is under way to elucidate the role of singlet molecular oxygen as an environmental oxidant. Specifically, the importance in photochemical smog of reactions which produce O2(1 delta) and which consume it will be evaluated. Spectroscopic techniques using a germanium photodiode detector sensitive at 1.27 microns are being used to determine the production of O2(1 delta) by four paths possible in real atmospheres: 1) direct absorption of actinic light, 2) oxygen- enhanced absorption of organic pollutants, 3) gas phase photosensitized reactions and 4) exothermic chemical reaction of ozone.

Absolute rate constants and mechanistic information are being obtained for the reactions of O2(1 delta) in the mm range with a variety of pollutants including olefins. The rates of total quenching of O2(1 delta) are followed by means of the germanium photodiode detector. In the ppm range, which simulates actual atmospheric conditions, long path length infrared (LPIR) techniques are being employed using chemical 'traps'. Studies on the possible effect of externally generated O2 (1 delta) on biologically significant molecules, bacteria, plants and plant tissue are being carried out.

Concurrently with the laboratory studies the relative importance of singlet oxygen, ozone and oxygen atoms as environmental oxidants will be evaluated. The results of this research will be applied directly to the problem of developing models for photochemical smog in real systems.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0871, PHOTOCHEMICAL REACTIONS IN A FLOW REACTOR
E.R. STEPHENS, Univ. of California, Air Pollution Research Center, *Riverside, California* 92507

This project is designed to investigate and compare synthetic and natural aerosols. Synthetic aerosols are prepared by a variety of techniques in a tube flow reactor which can be operated with or without ultraviolet irradiation. Techniques of aerosol generation range from simple vaporization of fuming sulfuric acid to irradiation of multicomponent mixtures such as olefin nitrogen oxides sulfur dioxide in air. In addition to gas chromatography and other techniques for measurement of gases and vapors, two major techniques are available for characterizing the aerosols. These are particle counting by light scattering and infrared study of impacted aerosol. The latter technique uses an impactor especially designed to maximize the efficiency of infrared analysis. Both techniques are applied to the natural aerosol of polluted air and to synthetic aerosol.

1.0872, IMPLEMENTATION OF A LABORATORY AUTOMATION SYSTEM
J. KRAUT, Univ. of California, Graduate School, *San Diego, California* 92038

The objective of this project is to assemble a versatile laboratory automation system. A general purpose digital computer owned by the Department of Chemistry of the University of California, San Diego, has been interfaced in a time sharing mode to several laboratory instruments. This will allow automatic control of several experiments and result in efficient accumulation and processing of large amounts of data. The automated system will greatly increase the power and scope of our experiments in high resolution X-ray structure of proteins, molecular beam studies of the chemical reactions of air pollution, and magnetic resonance studies of protein denaturation, which projects are funded by several individual research awards.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0873, AIR POLLUTION CHEMISTRY BY PHOTOFRAGMENT SPECTROSCOPY
K.R. WILSON, Univ. of California, Graduate School, *San Diego, California* 92038

By use of a new form of molecular spectroscopy which we have developed, photofragment spectroscopy, we propose to study in detail the photodissociation steps in air pollution. Specifically, we propose to determine, as a function of photon energy, the symmetries of the excited molecular states leading to dissociation, and the identities, translational and internal energies, and often the detailed distribution among internal states of the photodissociation fragments.

The technique of photofragment spectroscopy involves crossing a molecular beam of the molecules to be studied with pulses of polarized light from a laser and detecting the photodissociation fragments with a mass-spectrometer. The molecules which we propose to study are nitrogen dioxide, alkyl nitrites, ozone and various carbonyls.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0874, THE CHEMISTRY AND PHOTOCHEMISTRY OF AIR POLLUTANTS
A. HASSNER, Univ. of Colorado, School of Arts, *Boulder, Colorado* 80304

Nitro compounds and alkyl nitrates are recognized as contributors to air pollution. We propose to study the basic chemistry of representative nitro olefins and alkyl nitrates with emphasis on synthesis, reactions, photochemistry, stereochemistry and isomerizations.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0875, TRACER STUDIES IN AIR POLLUTION - SULFUR DIOXIDE
P. URONE, Uni.. of Colorado, Graduate School, *Boulder, Colorado* 80302

The photochemical reactions of sulfur dioxide in controlled atmospheres in the presence of moisture, nitrogen oxides, and hydrocarbons have not been unequivocally established as to reaction rates or reaction products. The relative roles of particulate matter and aqueous aerosols in the catalysis of the thermal heterogeneous reactions of sulfur dioxide in polluted atmospheres have also not been clearly established and in particular with respect to the reaction products formed. The possibilities of secondary or long-term sulfur dioxide reactions, as could happen in stagnant polluted atmospheres, need to be carefully checked.

It is desired to investigate these types of reactions in some detail. Radio-chemical tracer techniques using 35SO2 or 14C tagged compounds in combination with microchemical and specialized gas chromatographic methods will give valuable information both as to rates of reaction as well as type of reaction products formed. Such information is of value in establishing air quality criteria and emission standards.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0876, STUDIES OF O ATOM REACTIONS OF ATMOSPHERIC IMPORTANCE
R.B. TIMMONS, Catholic University of America, Graduate School, *Washington, District of Columbia* 20017

Work will continue on the reactions of oxygen atoms with low molecular weight organic compounds. Major emphasis will be focused on the oxidation of aromatic compounds, such as benzene and toluene. The absolute rate constants for these reactions will be determined by the measurement of the atom decay signals of the oxygen atom as followed by its electron spin resonance absorption. In addition product analysis of the reactant stream will be attempted using gas chromatographic and mass spectrometer techniques. There are at present virtually no data available on the chemical kinetics and mechanismsm of the reaction of oxygen atoms with aromatic compounds.

We also intend to employ the ESR technique to investigate the chemical kinetics of the reactions of O2(1 delta g) with various compounds. At present, the most promising reactions would appear to involve unsaturated molecules containing the methoxy group. It is hoped that these studies will lead to a better appreciation of the factors involved in the reactions of O2(1 delta g).

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0877, THEORETICAL AERONOMY

A.E. GREEN, Univ. of Florida, Graduate School, *Gainesville, Florida* 32601

Support is provided for theoretical studies of aeronomic phenomena, including 1) ionospheric heating and ionic composition, 2) nighttime F-region transport loss and airglow effects, 3) aerosol scattering, and 4) radiative transfer.

SUPPORTED BY U.S. National Science Foundation

1.0878, STATISTICAL METHODS IN AEROSOL STUDIES

R.A. BRADLEY, Florida State University, School of Arts, *Tallahassee, Florida* 32306

The literature on air pollution will be surveyed to collect statistical distributions of aerosols (inorganic as well as organic aerosols). The statistical validity, interrelationships, properties of these distributions and their applicability to descriptions of aerosol systems will be discussed. Emphasis will be placed on distributions involving both aerosol size and number of particles as random variables. The material will be prepared in a form suitable for publication as a review paper in one of the air pollution journals.

The effect of 'filtration' on statistical distributions will be studied. Filtration is defined to be any process that alters the statistical properties of an aerosol 'system'. For a given statistical description of such an aerosol system we will study the form of the distribution as modified by filters whose efficiency depends on (1) aerosol size, (2) aerosol velocity and (3) filtration duration. A second category of problems involves determining confidence limits on filter efficiency. Finally, the optimally efficient arrangement of sequences of filters will be studied. Some of this work will involve computer simulation.

The deposition of aerosols under coalescence will be considered as a stochastic process. A stochastic model with random aerosol input and settling effects will be studied. The statistical distribution of aerosols will be used as a measure of air pollution.

1.0879, PHOTOCHEMICAL STUDIES BY ESR SPIN TRAPPING TECHNIQUES

E.G. JANZEN, Univ. of Georgia, School of Arts, *Athens, Georgia* 30332

A technique is being developed for the detection and identification of gas phase free radicals. This involves having the radicals add to a nitrone function which produces a relatively stable nitroxide radical. The nitroxides give esr spectra which are characteristic of the radical trapped and can be detected at very low concentrations (approximately 10 to minus 7 M) due to the high sensitivities of esr spectrometers. Radicals can be detected at low pressures (approximately 10 to minus 3 mm Hg) by having the radicals flow over solid phenyl N-t-butyl nitrone in a vacuum line. The radicals add to the nitrone and produce the nitroxide. However at these pressures at room temperature the nitroxide volatilizes off the surface of the solid nitroxide and can be trapped in a liquid nitrogen down stream. We are using an esr tube for this trap and detecting the nitroxides produced by esr techniques. By this method methyl radicals have been detected from the photolysis of acetone, trifluoromethyl and pentafluoromethyl radicals from photolysis of the corresponding iodides, and 2-hydroxypropyl from the photolysis of 1:1 mixtures of acetone and isopropyl alcohol.

1.0880, CHEMISTRY AND PROPERTIES OF OZONIDES

P.R. STORY, Univ. of Georgia, Graduate School, *Athens, Georgia* 30601

The purpose of this research project is to investigate several aspects of the chemistry and properties of ozonides. Investigations concerning the mechanisms of ozonide reductions, photo- and thermochemistry of ozonides, and the photo- and thermochemistry of ketone peroxides will be continued. This research project is also concerned with gas phase photolyses and thermolyses of ozonides and peroxides. Examination of ozonide hydrolysis, both acid and base catalyzed, will continue.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0881, FORMATION OF NONVOLATILE PARTICULATES FROM ORGANIC VAPORS

C. ORR, Georgia Inst. of Technology, Engineering Experiment Station, *Atlanta, Georgia* 30332

This investigation is seeking (1) to establish the parameters under which particulates of low volatility are formed from low concentrations of a variety of organic vapors in air when exposed individually to X- rays or ultraviolet light, (2) to determine the chemical (polymeric) composition of particulates so formed, and (3) to elucidate the mechanism of the formation. Such physical parameters as time of exposure, vapor composition, and the resulting particulate size distributions have been inter-related; some tests for composition have been completed, but these results are not yet inclusive or conclusive; and the reaction mechanism, or mechanisms, remains to be established.

Since the atmosphere contains traces of organic vapors coming from many sources and is exposed to both X-ray and ultraviolet radiation, it seems inescapable that the experiments being conducted duplicate natural processes that contribute to air pollution.

1.0882, HOMOGENEOUS NUCLEATION IN CONTAMINATED ATMOSPHERES

C. ORR, Georgia Inst. of Technology, Engineering Experiment Station, *Atlanta, Georgia* 30332

The behavior in inert atmospheres of submicron condensation nuclei under changing humidities has been described in previous publications from this group. Current research is endeavoring to describe the influence of contaminating vapors on nuclei behavior. These vaporous contaminants are either condensed as molecular layers on particulate surfaces or absorbed by droplets into a homogeneous solution. The transport of moisture to or from the particulates during the processes of condensation or evaporation will thus be altered.

Several experimental procedures are being utilized so that particulates of a wide range of sizes can be studied. The relationships among droplet size, properties of the nuclei, relative humidity, the time required for the formation and disappearance of the droplets, and the composition of the atmospheric contaminations are being studied under conditions of changing relative humidity. The experimental results will be analyzed in accordance with theoretical considerations for the widest possible application.

1.0883, PHYSICAL CHEMISTRY OF AEROSOLS

F.T. GUCKER, Indiana University, School of Arts, *Bloomington, Indiana* 47401

Experimental studies involve rapid methods of determining light- scattering diagrams from single aerosol particles in milliseconds rather than minutes. For the diagrams, we will study both analog display on an oscilloscope and digital readout for storage in the the memory of a computer interfaced to the apparatus.

The theoretical studies involve calculations of light-scattering diagrams for particles of various refractive indices and sizes, for which our new methods are faster than the classical Mie equa-

tions. The matching of the measured and calculated diagrams will be studied for the number and angular positions of extrema and for intensity readings at different angular intervals in order to determine the size and eventually other parameters such as refractive index and shape of individual particles from the measurements.

1.0884, OXIDATION MECHANISMS ON SUPPORTED CHROMIA CATALYSTS
R.G. SQUIRES, Purdue University, School of Engineering, *Lafayette, Indiana* 47907

The long range goal of the proposed research is to simultaneously apply spectral, gravimetric and kinetic analysis to heterogeneous catalytic systems in order to gain a better understanding of the mechanism of the processes occurring on the surface of a catalyst during a chemical reaction. In this study we propose to make simultaneous gravimetric and infrared spectral studies during adsorption and also simultaneous kinetic and infrared spectral studies at reaction conditions during the oxidation of carbon monoxide and light hydrocarbons on a supported chromia catalyst.

Automobile exhaust emissions are a major source of hydrocarbons and oxides of nitrogen which react photochemically in the atmosphere to produce smog. Thus, our choice of catalyst and reactions was made because of the practical importance of catalytically reducing the emission of hydrocarbons and carbon monoxide in automobile exhaust, thereby eliminating our major source of air pollution in many of our cities. However, in addition to giving us a better insight into the oxidation mechanisms on supported chromia catalysts, the proposed study should result in techniques which will be applicable to many other catalytic systems.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0885, ANALYTICAL AND EXPERIMENTAL INVESTIGATION OF THE REACTION KINETICS OF MAJOR AIR POLLUTANTS
S.L. WITTIG, Purdue University, School of Mechanical Engin., *Lafayette, Indiana* 47907

The proposed study is a combined analytical and experimental effort to determine the kinetic data, i.e., frequency factors and activation energies, and the mechanisms of the gas phase reactions of major air pollutants. Based on studies currently under way, the decomposition of selected hydrocarbons and their reactions with nitric oxides in particular will be investigated.

A new experimental approach will be applied by using a single pulse shock tube in combination with a time-of-flight mass spectrometer and spectroscopic and interferometric methods. Thus inherent limitations of the classical physical-chemical methods can be avoided. Also the experimental parameters, especially temperature and pressure, can be varied in almost unlimited ranges. A comparison with the list of Air Pollution Control Research Grants, NAPCA, and the literature shows that the approach suggested is unique.

With the data obtained by the proposed research, a gap should be closed, which is the main barrier for successful work in pollution control and in related areas of human medicine, botany, meteorology, and design of industrial plants.

SUPPORTED BY Purdue University - Lafayette, Ind.

1.0886, DIFFUSION IN TURBULENT SURFACE LAYERS
V.W. NEE, Univ. of Notre Dame, School of Engineering, *Notre Dame, Indiana* 46556

The research proposed here is a combined study of analytical and experimental investigation on the turbulent diffusion of pollutants in a surface layer. The primary objectives of this research are: 1. To develope, with experimental verifications, a general theory of turbulent transport of mass and heat in the surface layer based on a new differential field turbulent theory of the principal investigator. 2. To establish a general computing program which can be used for - ground or elevated point, line, multiple points and area source -stable, neutral and unstable atmosphere, - smooth, rough and built-up surface, to obtain the pollutant distribution at all downstream locations, and serve as a realistic model for air pollution system analysis.

1.0887, NUMERICAL MODELING OF OXIDATION REACTION SCHEMES
J.T. DEHN, U.S. Army, Ballistic Research Labs., *Aberdeen Proving Ground, Maryland* 21005

Technical Objective: To model some of the sub-reaction in the general hydrocarbon oxidation problem. Not only will the carbon monoxide scheme be modelled but the effect of the addition of hydrocarbons to carbon-monoxide oxygen mixtures and the role of carbon- monoxide in hydrocarbon oxidations will be modelled.

SUPPORTED BY U.S. Dept. of Defense - Army

1.0888, TOXIC MATERIALS IN NUCLEAR SUBMARINES
P.P. DEMAS, U.S. Navy, Ship Research & Dev. Lab., *Annapolis, Maryland* 21402

Technical Objective: Conduct fundamental research studies to determine the outgassing properties and degradation characteristics of nonmetallic materials and to assess their contribution to atmosphere contamination in closed ecological systems. Information from these studies will generate the technical basis for the selection of submarine materials which will contribute minimally to the contamination of the atmosphere and hence effect a means of source contamination control.

SUPPORTED BY U.S. Dept. of Defense - Navy

1.0889, PHOTOSENSITIZED OXYGENATIONS
A. NICKON, Johns Hopkins University, School of Arts, *Baltimore, Maryland* 21218

Photosensitized oxygenation of mono-olefins is known to produce allylic hydroperoxides with the double bond adjacent to its original location. The reaction is attractive as a tool for organic synthesis and as a possible pathway for certain biological oxidations. By working with molecules of rigid geometry (e.g., steroids) and with deuterium labeled substrates we hope to get detailed information on the mechanism of the reaction including its geometric aspects. Through a study of secondary isotope effects we hope to define the geometry of the transition state and thereby to discriminate between a one-step cyclic mechanism and a two-step process involving discrete intermediates. The oxygenation reaction will be extended to hetero-containing systems (e.g., azines) to explore their behavior. Experiments are planned that could reveal how some sensitizers transfer energy to oxygen to produce excited oxygenating species. In view of the potential implication of excited oxygen in atmospheric reactions that create air pollutants and in pathways for biological oxidations, fundamental studies of all aspects of the properties and behavior of excited oxygen are particularly important.

1.0890, LABORATORY STUDIES OF NON-THERMAL ENERGY TRANSFER PROCESSES BETWEEN ATMOSPHERIC MOLECULES
R.E. MURPHY, U.S. Air Force, Cambridge Research Labs., *Bedford, Massachusetts*

Technical Objective: AF function - detection, surveillance, early warning, reconnaissance, and homing. Deficiency - optical infrared backgrounds interfere with detection systems, particularly during and after atmospheric nuclear explosions. Inadequate information concerning molecular/atomic processes contributing to the radiative character of the atmosphere. Research - laboratory studies of phenomena contributing to the generation, transfer, degradation and radiation of internal molecular energy. How research contributes - permits sensors to detect targets against a nuclear-induced optical/infrared background. The objective is to conduct controlled laboratory studies to determine the

mechanisms and character of excitation of atmospheric species, perform theoretical studies to describe the dynamic state, population, and spectral character of both equilibrium and non-equilibrium gases. Basic parameters are measured to allow the radiative condition of the atmosphere to be predicted and calculated under a variety of circumstances, particularly when disturbed by nuclear detonations

1.0891, THE RELATION BETWEEN IONIC AND RADICAL BOND CLEAVAGE
P.D. BARTLETT, Harvard University, School of Arts, *Cambridge, Massachusetts* 02138

New ways of generating singlet oxygen from ozone and from oxidation of secondary hydroperoxides are under investigation. An isotope-effect study is being made of competing or merging mechanisms in the ene and cycloaddition reactions of singlet oxygen. The special conditions under which biradicals may be captured are being studied. New free-radical initiators of azo and peroxy type are being made for controlled introduction of free radicals at low temperatures. The behavior of a monoallylic biradical which may close to a 6-ring is being scrutinized.

Syntheses involving cycloadditions of chloroketenes involve some characteristic rearrangements which are being further studied.

1.0892, DISPERSION OF AIR POLLUTANTS
J.A. FAY, Mass. Inst. of Technology, School of Engineering, *Cambridge, Massachusetts* 02139

A continuation of a theoretical and experimental study of the motion of buoyant plumes in a stratified atmosphere. The theoretical study incorporates fluid mechanical models of plume motion and leads to methods for correlating field observations of plume rise as well as laboratory model experiments. The laboratory experiments are measurements of mean plume motion in a small scale stratified flow wind tunnel (1' x 1' x 5'). The tunnel flow is thermally stably stratified.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0893, ELECTRICAL CHARGING OF SMALL PARTICLES AT LOW PRESSURES
B.Y. LIU, Univ. of Minnesota, School of Engineering, *Minneapolis, Minnesota* 55414 (AT)

Objectives. The objectives of the proposed work for the coming year include: (1) to study the statistics of the particle charging process in the transition and the free molecular regimes and the effect of the image force on the charging process. (2) To study the inertial deposition of aerosol particles in turbulent pipe flow with particular reference to the effect of the roughness of the pipe. (3) To study the filtration of aerosol particles by fibrous filters at low pressures.

Procedure. The charging studies will involve generating a monodisperse polystyrene latex aerosol, charging it under conditions of known ion concentration and charging time and precipitating the particles in a cylindrical mobility analyzer of high resolution. The resulting charge distribution will be measured by counting the deposited particles in a microscope. The results will be compared with values predicted by theory. The filtration studies will involve predicting the filter performance using the Kuwabara-Happel flow field and comparing with experimentally measured filter efficiencies at low pressures. The turbulent deposition studies will involve measuring the deposition velocities of aerosol particles as a function of particle size and comparing the results with a new deposition theory being developed.

Some preliminary data on the charging studies have been obtained. The results show that for the 0.5 micron diameter particles charged under conditions of diffusion charging the charge distribution is approximately log-normal with a geometrical standard deviation of approximately 1.1. This compares well with the theoretically predicted value of 1.08 for the geometrical standard deviation.

1.0894, CHEMISTRY OF SINGLET OXYGEN FROM OZONE SOURCES
R.W. MURRAY, Univ. of Missouri, School of Arts, *Saint Louis, Missouri* 63121

It has been shown that ozone reacts with a variety of organic substrates to generate singlet oxygen. This observation is of importance to the air pollution problem since ozone is a common and highly toxic pollutant. The reactions of singlet oxygen with various organic substrates will be studied. The substrates will include those which will permit us to study photodynamic action by comparing our reaction products with those obtained from photosensitized oxidation. Oxidation of simple disulfides using the triphenyl phosphite ozonide has been shown to give thiolsulfinates and thiolsulfonates. These products as well as the relative reaction rates will be compared to those obtained using photosensitized oxidation. The oxidation of alpha-lipoic acid and suitable derivatives of the DNA bases with singlet oxygen will also be studied.

1.0897, REACTIONS OF SO2 WITH HYDROCARBONS, CO AND H2
S.H. BAUER, Cornell University, School of Arts, *Ithaca, New York* 14850

Studies of homogeneous reactions in the gas phase at high temperatures between the pollutant SO2, which is a strong oxidizing agent, and reducing agents, of which CO and C2H2 are type representatives, have uncovered several interesting facts, as detailed below. During the coming year the single-pulse shock tube technique which has proved effective for the above investigations will also be used for exploring the SO2 plus H2 reaction. However, it appears that in this case single-pulse data will have to be augmented with spectroscopic data recorded during shock conditions, so that quantitative estimates of the instantaneous concentrations of SO2, OH, and S2 will be available to complement the analytical results on the quenched product gases.

The kinetic results obtained during the past twenty (20) months show that due to its great stability SO2 reacts only slowly with carbon monoxide or hydrocarbons at temperatures below 1700 degrees K and that the end products of such reactions are not the ones calculated by statistical thermodynamics. To

facilitate the low temperature conversion of CO to CO2, or C2H2 to H2O and CO2, while the SO2 is reduced to elementary sulfur heterogeneous catalysis will have to be used. At sufficiently high temperatures, when the SO2 does react, the expected products are obtained and plausible mechanisms for these processes have been developed.

1.0898, PERACETOXYL RECOMBINATION
M.J. GOLDSTEIN, Cornell University, School of Arts, *Ithaca, New York* 14850

The mechanism of peracetoxy radical recombination in the gas phase is being investigated by studying photo-initiated oxidation of 18 O- acetaldehyde. The behavior of acetoxy radicals in the gas phase is concurrently under investigation using 18 O-labeled acetyl peroxide.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0899, STUDIES OF AIRBORNE PARTICULATES OF SUBMICRON SIZE
G.H. KUBIE, Univ. of Rochester, School of Medicine, *Rochester, New York* 14620 (AT(30-1)-49)

The formation of many air pollutants is influenced by the presence of sub-micron sized particles acting as condensation nuclei. The object of this project is the study of the conditions of formation and of the properties of sub-micron particles formed in gaseous systems. Its aim is the development and testing of equipment for the controlled production of sub-micron sized aerosols and their study under a variety of conditions with special reference to their behavior as condensation nuclei and their assay by diffusion measurements. In this connection the formation of nuclei by the action of ionizing radiation on gases provide a model for their formation under natural conditions. The production of particles formed by the action of thoron gas on air and other gases will be a major object of study in this respect. The design and use of a thoron source giving dry gas uncontaminated by organic and other volatile components is a prerequisite for the scheduled work.

RESULTS: A method for the production of condensation nuclei by air blast atomization has been described (mean particle size 0.01 - 0.02 micron) and their measurement by the diffusion method has been studied with the use of a G.E. condensation nuclei counter. The effect of the pulsatory conditions imposed by the use of this counter have been analyzed and they have been shown to be of minor importance with the use of a parallel plate diffusion battery.

SUPPORTED BY U.S. Atomic Energy Commission

1.0900, ASPECTS OF CHEMICAL REACTIONS OF AIR POLLUTANTS
K. MOROKUMA, Univ. of Rochester, School of Arts, *Rochester, New York* 14627

Though it is well known that the photochemical smog formation is initiated by photodecomposition of nitrogen dioxide and partly of organic aldehydes or ketones, the nature of these primary photodissociation processes is not well understood or is rather confused experimentally. The object of the proposed research is to establish details of the kinetics of the processes theoretically.

The objectives of theoretical works are (1) calculation of the potential energy surfaces relevant to photochemical primary processes and (2) calculation of trajectories of the systems on these potential energy surfaces.

The first system we plan to study is formaldehyde. The excitation energy dependence of quantum yield or rate of two competing photodissociation processes leading to H plus HCO and H sub 2 plus CO, respectively, is to be studied. First, the potential surfaces of ground and excited states are calculated with an ab initio SCFCI method. Once the potential surfaces are obtained, trajectory studies on these surface will be carried out, which will clarify the mechanisms and energetical dependence of two processes as well as the product energy distribution.

Nitrogen dioxide and nitrous oxide will be next systems. For the former the shape of the reaction path and its relationship to the product energy and momentum distribution will be studied, and for the latter the identification of the actual photodissociation mechanism out of several possibilities will be emphasized.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0901, STUDY OF THE EFFECT OF CARBON MONOXIDE ON THE RATE OF PHOTOOXIDATION OF HYDROCARBONS IN THE PRESENCE OF ULTRAVIOLET LIGHT & OXIDES OF NITROGEN
J.J. BUFALINI, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Preliminary work in our laboratory has shown that the rate of nitric oxide oxidation in the presence of hydrocarbon-NOx and ultraviolet light is enhanced when CO is added to the system. Since urban atmospheres always contain considerable quantities of CO it is mandatory that the role of CO is understood in these systems. This study will cover the broad range of hydrocarbons and oxygenated hydrocarbons to determine the role of CO in these systems. Such factors as hydrocarbon consumption rate, NO oxidation, product formation, NO2 dosage, and oxidant dosage will be investigated in the presence and absence of carbon monoxide.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0902, EVALUATION OF THE EFFECTS OF SO2 AND NO ON THE PHOTOCHEMICAL REACTIVITY OF AIR PARCELS OF THE N.Y.C. - N.J. AREA
S.L. KOPCZYNSKI, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Dual air samples will be collected in large plastic bags, with one serving as the control sample and the other charged with a known amount of NO or SO2. The two bag samples will be irradiated simultaneously under identical conditions, except for the NO or SO2 concentration. The reactions will be followed with analyses for NO, NO2, SO2, individual hydrocarbons, peroxyacetyl nitrate, aldehydes, total oxidant, and ozone. The effects of NO and SO2 will be evaluated on the basis of rate of oxidation of NO, rate of loss of hydrocarbons, and production of total oxidant, ozone and other products of the reaction.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

1.0903, MEASURE AND COMPARE REACTIVITIES AND COMPOSITION OF AIR PARCELS FROM BAYONNE, LINDEN, WILLOWBROOK, AND BRONX (ABBREV)
S.L. KOPCZYNSKI, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Parcels of air from the various localities will be collected in large plastic bags and irradiated in situ with sunlight. Quantitative analyses will be made for specific reactants and products during the course of the irradiation. Ozone, total oxidant, NO2 and peroxyacetyl nitrate concentrations, dosages, and rates of formation will be related to initial concentrations of specific hydrocarbons, nitric oxide, SO2 and to ultraviolet light intensity.

1.0904, TRANSITION METAL CHEMISTRY OF TWO COMMON AIR POLLUTANTS
W.A. MCALLISTER, East Carolina University, School of Arts, *Greenville, North Carolina* 27834

The principal purpose of this study is to examine the relationship between bonding to a transition metal and the metal's activity as a catalyst. I propose to use far infrared spectroscopy to investigate this bonding in some model compounds. I have chosen carbonyl, nitrosyl, and mixed carbonyl nitrosyl complexes because of their possible usefulness as catalysts in anti-pollution devices, and because of their interesting bonding. The far infrared spectra will yield data on the force constants for the M-CO and M-NO bonds, an these force constants should be related to the metal's activity as a catalyst for the oxidation of CO to COsub2 and reduction of NO to nitrogen.

1. AIR QUALITY

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0905, ELEMENTARY REACTIONS IN POLLUTED ATMOSPHERES
G.R. MCMILLAN, Case Western Reserve Univ., School of Science, *Cleveland, Ohio* 44106

Certain elementary free radical processes occurring during photoinitiated oxidation in polluted air will be studied using the methods of photochemical kinetics. The reactions of alkoxy radicals with oxygen and nitrogen dioxide will be studied by photolysis of an appropriate alkyl nitrite in the presence of nitrogen dioxide and oxygen, and the competition followed by long path infrared spectrophotometry. The alkoxy-oxygen reaction has been suggested to be an important chain propagating step in the nitric oxide to nitrogen dioxide conversion and in the carbon monoxide cleanup cycle. This research may lead to assessment of the importance of this and other fates of alkoxy radicals in exhaust-polluted atmospheres.

1.0906, PHOTOCHEMICAL GAS-PARTICLE INTERACTIONS
G.R. MCMILLAN, Case Western Reserve Univ., School of Science, *Cleveland, Ohio* 44106

The work examines the chemical effects on gases following light absorption by solid particulates in contact with the gases. Electronic energy transfer to the gas at the gas-solid interface will be examined to determine the mechanism of the transfer, to define some of the experimental parameters in heterogeneous photochemical systems, and to determine possible chemical consequences of absorption of light by surfaces in contact with oxygen and typical pollutants.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0907, ELEMENTARY REACTIONS IN PHOTOCHEMICAL SMOG
W.E. WILSON, Battelle Memorial Institute, *Columbus, Ohio* 43201

The objective of this grant program is to contribute to the quantitative understanding of photochemical smog by measuring the reaction rates of some of the important elementary reactions. This involves four steps: (1) Measuring rate constants of elementary reactions thought to be important, (2) discovering new elementary reactions which are important, (3) developing techniques for measuring rates involving species such as OH, HO sub 2, delta O sub 2, RO sub 2, RO, R(CO)O sub 2, R(CO)O, (4) using the rates and mechanisms obtained in the program to predict the smog reaction path. The efforts of past years have been devoted largely to developing methods for measuring OH reactions and identifying new reactions and species which are important in photochemical smog.

Accomplishments during the first year include (1) development of techniques for measuring OH reactions; (2) experimental evidence for the conversion of NO to NO sub 2 by the chain reaction CO plus OH yields CO sub 2 plus H, H plus O sub 2 yields HO sub 2, HO sub 2 plus NO yields NO sub 2 plus OH; (3) discovery of a long lived radical which converts NO to NO sub 2 in the dark and which reacts with SO sub 2; (4) discovery of the reaction of SO sub 2 with the product of the NO sub 2 plus O sub 3 reaction; (5) the discovery that water vapor apparently plays an important role in the gas phase chemistry of photochemical smog; (6) development and use of a kinetic computer code for prediction of the smog reaction path.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0908, MECHANISMS OF PHOTOCHEMICALLY INITIATED OXIDATION
J.G. CALVERT, Ohio State University, School of Mathematics, *Columbus, Ohio* 43212

The major research objective of this investigation is the elucidation of the chemical reactions which occur in the usual polluted atmosphere. Three distinct areas of research contribute to the program: 1) The study of the mechanism of the photooxidation of various organic and inorganic compounds which are common contaminants of the various urban atmospheres (sulfur dioxide, formaldehyde, nitric oxide in olefin mixtures, etc.). 2) The characterization of the reactive intermediates and transients formed in these systems, and the quantitative determination of the rate constants for their various thermal reactions. 3) The use of these rate constant data, together with other available kinetic data, to test possible models of the reaction mechanisms operative in the real atmospheres using computer techniques.

1.0909, MATRIX-ISOLATED SPECTRA OF NITROGEN OXIDES
W.A. GUILLORY, Drexel University, School of Engineering, *Philadelphia, Pennsylvania* 19104

It is proposed to continue using the method of matrix-isolation to make a systemic study and identification of the stable and unstable oxides of nitrogen trapped in various environments at liquid helium/hydrogen temperature. The results of this study will not only prove valuable to the fields of spectroscopy and kinetics, but also to the problem of photochemical air pollution. It is well known that reactions involving oxides of nitrogen play an integral role in the production of air pollutants, however, the elementary processes and intermediates have proven difficult to ascertain. Our studies to date have indicated that this method is ideal in identifying some of these proposed intermediates. We have further observed that ultraviolet photolysis of selected stable molecules produces atomic species which are mobile in matrices, allowing characterization of elementary atomic mechanisms which occur in the atmosphere.

Therefore, investigation of these two facets of photochemical air pollution, i.e. identification of stable and unstable pollutants and the characterization of elementary processes resulting from photochemical absorption, is proposed.

1.0910, ATMOSPHERIC DIFFUSION OF RADON
H. NEWSTEIN, Drexel University, Graduate School, *Philadelphia, Pennsylvania* 19140

An understanding of the nature of the variability of the turbulent diffusion coefficients both in elevation and in time is essential for a rational program of effective air pollution control. To this end, a 1000 ft. TV tower has been instrumented and is currently in operation. Measurements of wind direction and speed, temperature, and concentrations of SO sub 2 and Radon are being made and recorded continuously and automatically at various elevations above the ground. Drexel Institute of Technology proposes to continue to measure these parameters over a sustained period of time so that statistically meaningful data may be obtained and used as the basis for the development of models of turbulent diffusion that will be more applicable to urban areas than are at present available. Intercomparisons will be made of the diffusion coefficients derived using different parameters so as to optimize the coefficients developed. A sufficiently long period of observations will permit the study of how these diffusion coefficients are related to a variety of synoptic situations, conditions of stability of the air and directions from which the wind is blowing in relation to the city and rural and urban areas.

1.0912, CONVERSION OF NO TO NO2 IN POLLUTED ATMOSPHERES

J.P. HEICKLEN, Penn. State University, School of Science, *University Park, Pennsylvania* 16802

We are attempting to find paths which convert NO to NO2 in urban atmospheres. We believe that two paths of importance are: (1) RO2 plus NO yields RO plus NO2, where RO2 is an alkylperoxy radical and (2) RO plus O2 yields R'O plus HO2; (3) HO2 plus NO yields HO plus NO2, where RO an an alkoxyl radical and R'O is an aldehyde or ketone.

Two systems have been examined. In one, CH3N2CH3 has been photo- oxidized to produce CH3O2 radicals. In the presence of NO, NO2 is produced. The pertinent reactions are: (1) CH3O2 plus NO yields CH3O plus NO2, and (2) 2CH3O2 yields 2CH3O plus O2. The predicted rate law for the quantum yield of NO2 production, phi(NO2), is phi(NO2) equals k6(NO/(k7Ia) to the one-half power, where Ia is the rate of absorption by CH3N2CH3 of the radiation. This law was obeyed and K4/k5 to the one- half power, was found to be (6.5 M to the minus one-half power) (sec to the minus one-half power). Rotating sector experiments will be done to obtain absolute values for the k4 and k5. Then azoethane will be examined to obtain the same information for C2H5O2 radicals.

In the second system, CH3ONO was photolyzed to produce CH3O radicals. In the presence of both O2 and NO, NO2 was produced in a manner consistent with reactions 2 and 3. Higher analogs of CH3ONO will be examined. Also the reactions of alkoxy radicals with CO, NO2 and SO2 will be studied.

1.0913, THE REACTON OF METALLOPORPHYRINS WITH AIR POLLUTANTS

J.C. FANNING, Clemson University, School of Arts, *Clemson, South Carolina* 29631

Metalloporphyrins play a vital role in biochemical processes of living matter. The metalloporphyrin molecules are planar, or nearly so, and their biochemical reactivity is, in many cases, due to their ability to add at least one molecule to the perpendicular positions about the molecular plane. Common air pollutants, nitrogen dioxide, nitric oxide, or sulfur dioxide, may react with, or add to, the metalloporphyrin and prevent it from functioning in its normal manner.

Solid metalloporphyrins, or related compounds, are to be reacted with the above gases at various temperatures and pressures, with and without the presence of moisture, and the products studied. The spectral and magnetic properties of the products will be measured. The reactions will be carried out in solution and comparisons made between the solid state and solution reactions. Of especial interest will be those metalloporphyrins which react in a reversible manner. The decomposition pressures of these adducts will be measured. This study should contribute to the understanding of the reactivity of common air pollutants with, and their bonding to, metalloporphyrins.

1.0914, TURBOPROPULSION AUGMENTOR EXHAUST EMISSIONS INVESTIGATION

L. CRAWFORD, Univ. of Tennessee, School of Engineering, *Knoxville, Tennessee* 37916 (F33615-71-C-1125)

Technical Objective: This effort will develop an analytical model of the combustion process in the afterburning system of a turbine engine, to predict its exhaust emission characteristics. The model will be capable of describing specifically the formation and extinction characteristics and the concentration levels of the undesirable and toxic exhaust products.

SUPPORTED BY U.S. Dept. of Defense - Air Force

1.0915, DYNAMICAL THEORIES OF KNUDSEN AEROSOLS

J.R. BROCK, Univ. of Texas, School of Engineering, *Austin, Texas* 78712

The objective of work done under AP00479 is to describe in as rigorous manner as possible the processes involved in the nucleation, growth, and transport of aerosol particles in the submicron size range. Two important areas are receiving particular attention. One is concerned with accurate descriptions of the changing rates and total change as a function of time of submicron aerosol particles in the presence as well as in the absence of external electric fields. The effects on the charging rate of the image force, polarization, and non- equilibrium ion velocity distribution functions are all under consideration in the theoretical description. The other area receiving extensive investigation concerns the size distributions of aerosols and of the atmospheric aerosol in particular. Stochastic models yielding the so-called Junge distribution for the size of continental aerosols are being studied.

1.0916, THE REACTION OF O('D) ATOMS WITH WATER VAPOR

B.A. DEGRAFF, Univ. of Virginia, School of Arts, *Charlottesville, Virginia* 22903

The objectives of this research are to determine the relative rates of reaction for the various reactions of O('D) atoms in the photolysis of moist ozone, to test which of the several possible mechanisms is responsible for the chain decomposition of moist ozone, and finally to learn as much other detailed information about the system as the techniques of flash and kinetic spectroscopy will allow.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

1.0917, LASER ANEMOMETER STUDY OF TURBULENT DIFFUSION AND TURBULENT SHEAR FLOWS

J.B. MORTON, Univ. of Virginia, School of Engineering, *Charlottesville, Virginia* 22903

The primary aim of this research project is to advance the basic understanding of inhomogeneous turbulence and the turbulent diffusion process. A laser anemometer will be used to measure statistical properties of turbulent shear flow in a wind tunnel and to measure local, instantaneous particle concentrations.

SUPPORTED BY U.S. National Science Foundation

DESCRIPTION OF RESEARCH TASKS

2. WATER QUALITY

A. SOURCES OF POLLUTION

Projects Concerned Primarily With the Origin of A Water Pollutant (e.g., Eutrophication, Environmental Cycling, Runoff, Erosion, and Sedimentation). Includes Unusual Pollutant Sources Or Special Interest Sources (e.g., Oil Spills, Trace Element Pollution, Dredging, Rain-atmosphere Washout, Radioactive Fallout).

2.0001, DYNAMICS OF ALGAE POPULATIONS IN FARM FISH PONDS

J.M. LAWRENCE, Auburn University, Agricultural Experiment Sta., *Auburn, Alabama* 36830 (ALA00287)

OBJECTIVE: Determine the seasonal abundance of various algae in ponds with different levels of fertility. Determine the seasonal macro and micro nutrient composition of filterable suspended matter, the filtered water, and the hydrosol from ponds with different levels of fertility. Determine changes in nutrient and algal species composition associated with different algal control practices. Investigate techniques for management of algal species in ponds with different levels of fertility.

APPROACH: Samples of water, suspended matter and hydrosol will be collected from unfertilized, fertilized and fed fish ponds at various times throughout the year. Algae will be identified and its inorganic chemical composition determined. Inorganic composition of waters and hydrosols will also be determined. Changes in algal associations and chemical composition resulting from chemical and biological control practices will be investigated. Data accumulated in above investigations will be evaluated by appropriate statistical methods. Based upon data accumulated above, techniques for selected desirable phytoplankton and subsequent seeding into ponds will be investigated.

PROGRESS: Techniques to estimate the standing crop of major plant nutrients (N,P,K) in a farm pond were employed on a number of experimental ponds. The standing crop of nutrients within a 22-acre pond, which had received 51,500 lbs. of organic fish feed in the prior 7-month growing season are given below. Of the total 150 lbs/a N added in feed, 8.5 lbs/a was in solution, 15.6 lbs/a was in suspended matter (phytoplankton), and 46.9 lbs/a was in catfish. The other 79 lbs/a N was lost to air and soil. Of the total 18 lbs/a P added in feed, 1.2 lbs/a was in solution, 4.3 lbs/a was in suspended matter, and 17.3 lbs/a was in catfish. The 4.8 lbs/a P deficit was apparently supplied by the soil. A total of 26 lbs/a K was added in feed, but 48 lbs/a was in solution, 4.5 lbs/a was in suspended matter, and 2.6 lbs/a was in catfish. The 29.1 lbs/a K deficit was apparently supplied by soils in pond and watershed. The suspended matter (phytoplankton) was 95% Microcystis sp., with Rhaphidiopsis sp., Oscillatoria sp., and Spirulina sp. making up the other 5%.

SUPPORTED BY U.S. Dept. of Agriculture

2.0002, ENTERIC VIRUS SURVIVAL IN ESTUARINE WATERS

E.W. AKIN, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Dauphin Island, Alabama* 36528

This project is concerned with determining the survival characteristics of human enteric viruses in the hydrosphere. This includes, but is not limited to, drinking water, recreation waters, and reclamation waters. The fact that enteric viruses continuously pollute the waters and waterways of our nation is not only empirical but also has been substantiated by experimental observations. Sound judgements regarding the role of water in the transmission of diseases by viruses is virtually impossible without critical knowledge of their survival in the water environment. The intent of this project is to provide definitive information on virus survival so that a realistic indication of the health hazards of viruses in water may be intelligently assessed. Initially, survival characteristics of four human enteric viruses (coxsackie virus B-1, echo virus 6, reovirus 1, and polio virus 1) will be compared in laboratory studies with waters having various characteristics. Consideration will be given to such factors as adsorption, aggregation, temperature, and salinity, to name a few. Survival studies of selected enteric viruses will also be conducted under quasi-natural conditions of estuaries. This project was started in January 1969 and is continuing.

2.0003, DEVELOPMENT OF A HYDROLOGICAL CONCEPT FOR THE GREATER MOBILE METROPOLITAN-URBAN ENVIRONMENT

G.M. LAMB, Univ. of South Alabama, School of Arts, *Mobile, Alabama* 36608

The specific objectives of the research proposed are to study the hydrologic system, both the surface and the groundwater systems, of the greater Mobile metropolitan-urban area and its environs. The information gained will assist in the formulation of adequate procedures for the orderly development and management of the water resources of the area. Qualitative and quantitative hydrologic methods of study will be used to provide data necessary to evaluate the amounts of surface and ground water available for development. Existing salt water encroachment problems will be studied and potential areas of these problems will be defined and evaluated.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0004, FATE OF TRACE-METALS (IMPURITIES) IN SUBSOILS AS RELATED TO THE QUALITY OF GROUND WATER

W.E. NELSON, Tuskegee Institute, Graduate School, *Tuskegee Institute, Alabama* 36088

The proposed research involves laboratory and field studies directed at securing information linking the interaction of fertilizers applied to agricultural lands and the movement of the applied cations in run-off and ground water, the quality of drainage water, and the physicochemical properties of soils. Leaching columns will be used in the laboratory in simulating field conditions to study the following variables in relation to the movement of metal ions: (1) soils of different texture, cation exchange status, organic matter content, and pH; (2) different moisture regimes-continuous leaching with cation free water and solutions containing the metal ions in increments, after equilibrium has been established. The content of metal ions in surface (run-off) water and the water which reappears in streams, creeks, lakes, and wells will be determined. This will be correlated with the content of metals in the soils at varying depths of the watersheds associated with the sampled waters.

Laboratory and field data will be compared for final interpretation of the fate of trace-metals in subsoils, and their relationship to the quality of ground water.

2.0005, FATE OF HARMFUL METALS IN SOIL AND WATER SYSTEMS
W.E. NELSON, Tuskegee Institute, George W. Carver Res. Found., *Tuskegee Institute, Alabama* 36088

Laboratory observations have suggested that the interactions of zinc ions with the organic matter of two soils varying widely in genesis, and physical and chemical properties were ion-exchange, surface absorption, coagulation, precipitation, and chelation. Further observations have also shown that the mechanism of retention for part of the metal in the soil was similar to a molecular sieving action observed for Sephadex. The investigation proposed herein is prompted by the idea that all metal ions can undergo a similar entrapment by molecular sieving. Thus the experiments are especially designed to shed more light on this mechanism, and thereby to subsequently make recommendations for its use as a means of suppressing the uptake of radioactive metals by plants. The proposed program has the more specific goals: (1) To secure more evidence on the formation and nature of organic-metal compounds in soil; (2) To investigate more thoroughly the molecular sieving action of soil, Sephadex, and other organic substances in retaining metals in an insoluble, non-displaceable, or unavailable state; (3) To observe the rate of breakdown of the organic- metal insoluble systems by micro-organisms usually present in the soil environment.

To meet these objectives a thorough study will be made of the reactions of different soils, Sephadex, water insoluble chelating and complexing agents, and sequestering agents with metal ions. It is proposed to relate the mechanisms of metal absorption to the structures of the ligand molecules and in so doing these structure correlations can be extended to other systems.

2.0006, CONTROL OF IRON BACTERIA IN WATER WELL SYSTEMS
R.M. ALVERSON, State Geol. Survey, *University, Alabama* 35486

The purpose of the project is to study the sources and accumulation of iron bacteria in water well systems and to experiment with mechanical, physical, chemical, and biological control systems. The studies are being undertaken in an area having a known iron bacteria problem. Various types of well screens will be installed and an attempt will be made to isolate and identify iron bacteria from field samples. A model laboratory system will be developed in an attempt to duplicate field conditions.

2.0007, TOTAL ORGANIC CARBON AS A POLLUTION CONTROL PARAMETER IN SUB-ARCTIC WATERS
E.W. MUELLER, U.S. Dept. of the Interior, Federal Water Quality Admin., *College, Alaska* 99701

Organic materials are one of the major sources of natural pollutants in arctic waters. The scope of this research is to evaluate a number of methods for determining the concentration of organic materials in the natural waters of Alaska. The approach will involve a series of experiments with oxidation of the organics to carbon dioxide and measurement of the carbon dioxide in a non-dispersive infrared analyzer. Combustion will be accomplished both at high temperatures in a stream of oxygen, and through wet chemical oxidations. Typical compounds will be used as standards to determine the effectiveness of the method. Comparison will be made between chemical oxygen demand of field samples and the values found by total carbon determination.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0008, PATHWAYS OF TRACE ELEMENTS IN ARCTIC LAKE ECOSYSTEMS
R.J. BARSDATE, Univ. of Alaska, Inst. of Marine Sciences, *College, Alaska* 99735 (AT(04-3-310.PROJ.04)

This project is concerned with the geochemical cycling of metals, the effect of biological activity on this cycling and the relationship between the forms in which metals occur and their ecological significance.

The metals under study are copper, cobalt, iron, manganese and zinc, and, to a lesser extent, the more abundant cations of natural waters. The objectives are to identify or define chemically distinct metal compartments (which consist of the various species in the water and particulate phases), to measure the amount and rate of transfer of metals in these compartments, and to determine the factors and processes responsible for the observed distributions.

Quantitative determinations of trace metals are made by anodic stripping voltammetry (for Cu and Zn) and by atomic absorption (Cu, Co, Zn and some Mn and Fe samples are preconcentrated). Dialysis, gel filtration, radioactive tracers and electrochemical methods are used in combination with the quantitative determinations for the study of metal binding by organic ligands, and when necessary, organic complexes are destroyed by photochemical (UV) oxidation or persulfuric acid digestion. The distribution of exchangible metal between dissolved and particulate (e.g. clay) phases is measured with tracer techniques.

Dissolved organic complexes of transition metals have been detected in all high latitude lakes so far examined, but they are dominant only in colored, organic-rich waters. Other recent findings indicate that the processes of complexation by organics and sorption by clays interact through competition for dissolved metals present in simple inorganic forms.

2.0009, DYNAMICS OF THE NITROGEN CYCLE IN LAKES
V.A. BILLAUD, Univ. of Alaska, Inst. of Marine Sciences, *College, Alaska* 99735

The transformation rates within the freshwater biological nitrogen cycle are under investigation using the stable isotope of nitrogen, 15N as a tracer. The role of the nitrogen cycle in the productivity regimes of lakes, in bloom development, in under-ice winter metabolism are all included. The role of denitrification is emphasized, as well as nitrogen fixation, both under aerobic and anaerobic conditions. Possible heterotrophy or mixotrophy under winter and spring ice-cover are investigated using tritium labeled organic compounds. Gas chromatography is being used to study gas production during anerobic metabolism in lake waters. Detailed limnological studies of lakes in the subarctic are concurrently being carried out.

2.0010, THE INFLUENCE OF DECOMPOSING SALMON ON WATER CHEMISTRY
J.J. GOERING, Univ. of Alaska, Inst. of Water Resources, *College, Alaska* 99735

Waters of high ammonia content have been observed in the vicinity of seafood processing plants. High ammonia levels have also been observed in the estuaries of Southeast Alaska following the entrance of the salmon into the freshwater streams to spawn. Approximately fifty per cent of the Pacific salmon (Oncorhynchus sp.) biomass returns to the estuaries in the form of organic decomposition products. The decomposition and remineralization of these waste products can alter the nutrient chemistry and ecological environment of the estuary, and possibly of larger water masses. This project shall study the biological and chemical dynamics of the decomposition of salmon carcasses, both in fresh water and in an estuary. Studying this decomposition phenomenon in a natural environment will, hopefully, elucidate the rates and mechanisms of the chemical transformations that accompany the breakdown of fish flesh. It might also reveal the capacity of the ecosystem to handle quantities of organic seafood wastes without presenting a pollution problem.

The high protein content of fish flesh suggests that nitrogen studies would be an effective method for following the decomposition. Water chemistry studies on nutrient concentrations and additions will be performed prior to, during, and following spawning. In vitro studies on the products of decomposition of fish flesh will be carried out in the laboratory. Marine productivity and fertility experiments will be conducted using C14/labeled bicarbonate, chlorophyll determinations, and N15 labeled compounds. An attempt will be made to correlate metabolite concentrations of freshwater with the survival of salmon eggs. The infor-

mation should be directly applicable to the potential problem of pollution by seafood waste disposal.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0011, DISTRIBUTION OF ORGANICS FROM SALMON DECOMPOSITION

J.J. GOERING, Univ. of Alaska, Inst. of Marine Sciences, *College, Alaska* 99735

This investigation will be concerned with the distribution and fate of the organic material resulting from salmon-carcass decomposition. Preliminary studies were concerned with rates and mechanisms of the chemical transformations that accompany the breakdown of fish flesh, and the resultant effects on the water chemistry of the receiving estuary where decomposition and deposition take place. At this time, it is proposed to determine remineralization rates and transport mechanisms for the organic compounds resulting from the step-wise decomposition process. Attention will also be directed to an investigation of the estuary sediment to determine its composition. The approach will be through the use of 15N-labeled compounds and the 12C/13C isotope ratio and tracer technique, as well as through an intensive water-chemistry study.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0012, DOMESTIC WASTE DISCHARGE INTO A SILT LADEN ESTUARY

R.S. MURPHY, Univ. of Alaska, Inst. of Water Resources, *College, Alaska* 99735

Waste discharges into Cook Inlet, Alaska will be studied to determine their effect upon waters of a far-northern, glacial silt laden, partially ice covered estuary. Existing raw waste outfalls will serve to define the extent of pollution in these waters as compared to nearby but unpolluted regions of the inlet.

Extensive physical, chemical, and biological information is to be gathered and analyzed, its ultimate use to be predictive efforts on the ability of far-northern glacial fed estuaries to assimilate domestic wastes and to determine the degree of treatment which these wastes must be subjected.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0013, CONTROL OF EROSION AND SEDIMENTATION FROM ROAD BUILDING AND LOGGING--ALASKA COASTAL FORESTS

A.E. HELMERS, U.S. Dept. of Agriculture, Pac. N.W. For. & Rg. Exp. Sta., *Juneau, Alaska* 99801 (PNW1604)

OBJECTIVE: Determine factors related to erosion and soil mass movement, streambed characteristics, and water quality and yield; develop measures to improve these elements and salmon spawning habitat.

APPROACH: Studies will be made on salmon streams: effects of watershed characteristics and forest management practices on stream temperature, stream bottom fauna, and fish populations; soil stability: plant-soil stability relationships, effect of timber management on soil movement, and evaluation of stabilizing treatments; hydrology: soil moisture flux, precipitation, and potential evapotranspiration.

PROGRESS: Evidence of two late-Pleistocene glacial advances was found in Maybeso Creek valley. The younger till was deposited by glaciation of regional extent representing the last major glacial advance of classical Wisconsin age in southeast Alaska. The older till may also represent a regional glaciation, tentatively correlated with an intermediate to early-late Wisconsin age. Numerous debris avalanches have occurred in the younger till, many of them accelerated by timber harvesting. Shade is an important factor in maintaining the coolness of streams on clear sunny summer days. On clear sunny summer days the stream temperature increase per 20-yard reach without shade ranged from 0.02 C. to 0.21 C. and in shaded reaches the stream temperature decreased from 0.03 C. to 0.18 C. On overcast summer days the mean temperature increase per 20-yard reach in several streams in each of two areas was 0.011 C. and 0.009 C. Climatic data for 315 stations were analyzed by Thornthwaite's methods to characterize the climates of Alaska and develop a generalized map of potential evapotranspiration. The climates of Alaska range from perhumid warm microthermal in the coastal belt, semiarid warm microthermal in the central interior basin, which is the 'typical' Alaska climate, to semiarid tundra along the Arctic coast. The distribution of natural vegetation coincides reasonably well with estimated potential evapotranspiration.

SUPPORTED BY U.S. Dept. of Agriculture

2.0014, BEHAVIOUR OF RADIONUCLIDES IN MARINE BIOTA

D. BENINSON, Comision Nac. De Energia Atom., *Buenos Aires, Argentina*

Work carried out so far refers to the quantitative determination of the upttake of radiostrontium and radiocesium by several marine species. In the present period it is proposed to extend the work to other species, measuring the Cs-137 concentration factors in laboratory conditions and the strontium-to- calcium discrimination factors through determinations of stable strontium contents in field conditions.

In addition, it is proposed to initiate laboratory work for the determination of concentration factors of other fission products (Ce-144 and Ru-106) and of an activation nuclide (Co-60).

The following species will be studied: Fishes--Austromenidia argentinensis, Percophis brasiliensis, Nautopaedium porosissimus, Merluccius merluccius hubbsi, Eugralis anchoita, Scomper japonicus marplatensis, Cynoscion striatus, Micropogon opercularis. Crustacea-- Hymenopenaeus mulleri, Artemesia longinaris, Pagurus sp, Platixantus crenulatus. Mollusks--Mytilus platensis, Mesodesma mactroides. Algae-- Codium decorticatum, Rhodymenia, Jania rubens, Ulva lactuca.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

2.0015, BLUE-GREEN ALGAE AS A SOURCE OF WATER CONTAMINATION

T.J. MCMICHAEL, State Game & Fish Department, *Phoenix, Arizona* 85023

Objectives: To describe the distribution of blue-green algae on the Three Bar Wildlife area. 1. Collect and preserve samples of algae from water sources on the Three Bar during the summer months. 2. Identify the algae to determine if any of them are known toxin producers.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0016, SEDIMENT YEILD FROM RANGELAND WATERSHEDS IN THE SOUTHWEST

K.G. RENARD, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Tucson, Arizona* (SWC-014-GTU-1)

OBJECTIVE: Develop methods for predicting sediment amounts, types, and delivery characteristics from agricultural watersheds of varying sizes, physiography, land use and management.

APPROACH: Establish factors governing amounts and types of sediments produced and their transport. Determine sediment loads in streams and deposited in reservoirs, relating these to rainfall, runoff, topography, geology, soils, land use, and cultural practices. Identify and evaluate production of various types of sediment sources areas, and determine and characterize sediment delivery processes to derive improved equations for estimating sediment yields.

PROGRESS: Observations have shown that the water yield of semiarid areas is greatly affected by sediment deposition in the channels of the watershed as well as in the channels of the major streams to which the watershed may be tributary. Erosion control and sediment movement control into major tributary channels from semiarid watersheds is of great importance to sustained downstream water supplies, as well as to the sustained capability of semiarid rangelands to produce forage. Quantitative changes in the dissolved solids carried in the runoff water on the Walnut Gulch watershed in southeastern Arizona can be accounted for and predicted by knowledge of the source areas receiving rainfall

and possibly by the rainfall itself. Primary soils and the alluvium derived from recent igneous rocks yield runoff higher in potassium and phosphate. One area high in dolomitic material yields a magnesium-rich water. Partitioning of runoff from complex areas is accomplished by a computer program. Investigations on a sediment concentration rating curve in ephemeral streams have been only partly satisfactory. Using purely statistical techniques, the concentration at any time was related to a number of independent parameters descriptive of the flow conditions. Coefficients of determination of about 0.5 to 0.75 were obtained for multiple equations in this work.

SUPPORTED BY U.S. Dept. of Agriculture

2.0017, TRACE AND TRACER ELEMENTS IN GROUND WATER: PHASE III

G.R. DUTT, Univ. of Arizona, Agricultural Experiment Sta., *Tucson, Arizona* 85721 (ARZT-5301-952-149)

OBJECTIVE: Determine the Fe, Mn, Cr6, Ni, Cu, Zn, Pb, Cd, Co, Sr and L concentration in groundwater and effluents from cites, industry and agriculture, study changes in concentration of the above during groundwater recharge, determine factors in soil effecting the concentration of the above and evaluate the above as tracer ions in groundwater.

APPROACH: Water from groundwater and waste effluent sources will be analyzed for the above ions using atomic absorption techniques. Water moving through soils during recharge will be analyzed. Lysimeters will be used to study changes in concentrations. Solubility products for different minerals will be compared to those found in groundwater and soil extracts. A map of iso-chemical classes based on different criteria will be prepared to see if flow regimen in Tucson Basin can be characterized.

PROGRESS: The trace element composition in groundwaters in Arizona was studied. The effect of recharge on the composition of water was determined. The distribution and movement of ions in the Tucson Basin was investigated.

SUPPORTED BY Arizona State Government

2.0018, LIMNOLOGICAL EFFECTS OF ORGANIC WATERSHED LITTER

W.J. MCCONNELL, Univ. of Arizona, Graduate School, *Tucson, Arizona* 85721

An understanding of some important and unique watershed effects on small impoundments in the semi-arid Southwest is sought. The effects for which elucidation is proposed relate to the interaction of a flashflood drainage regime, great seasonal differences in rainfall and the intensely cyclical deposition of organic watershed litter in lakes of the region.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0019, HYDROLOGICAL AND ENVIRONMENTAL CONTROLS ON WATER MANAGEMENT IN SEMIARID URBAN AREAS

S.D. RESNICK, Univ. of Arizona, Water Resources Research Ctr., *Tucson, Arizona* 85721

The objectives of the proposed study are as follows: 1. To initiate and continue rainfall and runoff studies for selected semiarid urban and suburban watersheds relative to differing development intensities and types (residential, commercial and industrial) and to analyze the quantitative effects of various catchment surface properties on runoff under various intensities and duration of rainfall. 2. On a preliminary basis, to establish appropriate sampling criteria, and to sample and analyze the urban runoff for dissolved and suspended organic and inorganic material in order to provide a basis for the evaluation of potential pollutional effects on ground waters of the basin; and to initiate exploratory studies for treatment methods, such as filtration through natural soil or laterally through stands of grass, in the control and management of urban runoff waters. 3. To evaluate the environmental influences on water yield and quality as a basis for investigation of feasible design criteria for storm sewers, water control structures, or drainage and treatment facilities, in order to effect salvage and use of urban runoff and possibly to alleviate existing or potential hazards to public health or safety.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0020, MECHANISMS OF BIOLOGICAL LUXURY PHOSPHATE UPTAKE

I. YALL, Univ. of Arizona, School of Liberal Arts, *Tucson, Arizona* 85721

The objectives of the project are to study the factors and mechanisms involved in the luxury uptake and retention of phosphorus by activated sludge and its bacterial population.

It is proposed to deal with four main aspects of the problem. The first aspect involves studies on the phosphorus uptake, retention, and metabolism of Tucson sludge. This will involve isolating and identifying the radioactive compounds from the sludge exposed to P32 for up to six hours under 'fill and draw' conditions. High voltage electrophoresis, paper chromatography, column chromatography with various ion exchange and ion exclusion resins, and linear gradient centrifugation procedures will be employed.

Other aspects include: 2) Studies on a known strain of 'Zoogloea ramigera', a bacterium which has been reported in various activated sludges; 3) a study of isolated sludge bacteria. We have isolated 85 pure cultures and have developed a screening procedure wh ich compares and classifies an organism's ability to take up P32 from sewage; 4) a survey of sludges from other parts of the country. The screening procedure will permit testing the phosphorus uptake capability of about 40 isolates per week. A computer program will be developed to aid in classifying these bacteria.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.0021, LIMNOLOGICAL, ICHTHYOLOGICAL, AND PARASITOLOGICAL INVESTIGATIONS ON ARKANSAS RESERVOIRS IN RELATION TO WATER QUALITY

P.M. JOHNSTON, Univ. of Arkansas, Water Resources Research Ctr., *Fayetteville, Arkansas* 72701

The overall objective of this investigation is to evaluate the effects of impoundment and ageing and/or eutrophication of selected Arkansas impoundments on limnological, ichthyological and parasitological water qualities during the past 30 years.

The limnological investigation is to monitor physico-chemical and plankton parameters and to compare with those of the past 30 years. Qualitative and quantitative fluctuations of the plankters will be correlated with the abiotic factors to understand the seasonal cycles. Standardized methods will be employed in the determination of the physico-chemical factors.

The ichthyological study is to determine qualitative and quantitative aspects of te feeding biology of largemouth bass in relation to available food. Seasonal and annual growth rates, length- weight relationship, and condition factor will be studied in relation to abiotic and biotic factors. Standing crops of fish will be evaluated in relaton to physico-chemical factors and plankton.

The parasitological investigation is to study the qualitative and quantitative aspects of the helminth and crustacean parasites of selected game fishes. Effects of parasitism on the fish's condition factor and the overall interrelationships between these aspects and the abiotic and biotic factors will be evaluated to understand the decline in fishing success with the aging of reservoirs.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0022, A STUDY OF PHYTOPLANKTON DYNAMICS IN LAKE FAYETTEVILLE AS A MEANS OF ASSESSING WATER QUALITY

R.L. MEYER, Univ. of Arkansas, Graduate School, *Fayetteville, Arkansas* 72701

The proposed research plan involves an investigation of the algae as primary producers in a lake typical to northwestern Arkansas, Lake Fayetteville. The investigation will include field and laboratory analysis of the chemical, physical and biological factors effecting algal biomass, primary productivity and algal succession.

Field investigations include observation on: 1. The abiotic and biotic factors effecting primary productivity in an intensively studied lake. 2. Samplings from similar lakes will be compared with base lake.

Laboratory investigation would employ isolated and cultured naturally occurring algal species: 1. To identify the parameters to which influence the presence or absence and growth rate. 2. To identify those factors which determine its life cycle.

Field and laboratory data would be correlated to determine which parameter are the most applicable in influencing primary productivity and water quality.

2.0023, A PRELIMINARY ECOLOGICAL SURVEY OF DARDANELLE RESERVOIR PRIOR TO NUCLEAR FACILITY EFFLUENT DISCHARGE

C.B. SINCLAIR, Univ. of Arkansas, Water Resources Research Ctr., *Little Rock, Arkansas* 72204

The proposed research plan involves laboratory and field investigations directed at the determination of biotic and abiotic parameters of Dardanelle lake water before its utilization as condenser coolant in a nuclear power station. The main approach in the investigation is to observe and analyze the thermal, chemical, and some biological qualities of the water adjacent to the nuclear facility.

Field investigations at the lake would include observations from the following operations: 1. On site measurements of D.O., temperature, pH, and conductivity. 2. Collection of plankton by use of plankton nets. 3. Collection of invertebrate organisms using dredges, multiple plate samplers, and emergence traps.

Laboratory investigations in the University laboratory would employ the following methods: 1. Chloride ion, nitrate ion, phosphate ion, and chemical oxygen demand using specific ion and/or spectrophotometric methods. 2. Qualitative and quantitative determinations of plankton. 3. Qualitative and quantitative determinations for the benthnic fauna.

The laboratory and field data would be correlated to show base line values for the physico-chemical parameters of Dardanelle Reservoir prior to plant activation.

2.0024, THE LIMNOLOGY OF LAKES FORMED BY BAUXITE STRIP-MINING OPERATIONS

G.L. HARP, Arkansas State University, Graduate School, *State University, Arkansas* 72467

The process of strip-mining coal commonly leaves pits which subsequently fill with water. These strip-mine lakes occupy over 65,000 acres of land in Arkansas, Missouri, Oklahoma, Kansas, and Iowa. Initially, many such lakes contain water contaminated with sulfuric acid formed from the oxidation of sulfur compounds associated with the coal. High concentrations of hydrogen ions severely limit the biota in such waters. The acid pollution may render the water and surrounding lands unproductive as regards fish, crops or grazing of domestic animals, for in excess of 50 years.

In contrast to the extensive literature concerning strip-mining for coal, no investigation has been conducted to date concerning the physicochemical or biological characteristics of strip-mine lakes resulting from bauxite mining. This process also results in acid water and polluted landscape.

The purposes of this study are to qualitatively and quantitatively describe the physicochemical characteristics and the aquatic flora and fauna of strip-mine lakes resulting from bauxite mining. Further, this information will be compared with that known concerning coal strip-mine lakes.

2.0027, STUDY AND IMPROVEMENT OF BIOSPHERE RESOURCES. 1. INFLUENCE OF MERCURY IONS ON DNA-REPAIR AND RECOVERY OF ALGAE

H. ALTMANN, Austrian Atom. En. Study Group, *Vienna, Austria*

Mercury pollution has now become a dangerous problem in some areas. Industrial wastes containing inorganic mercury find their way into lakes, in which it is converted by anaerobes to methylmercury. This highly toxic substance can also produce mutations. Direct interaction of mercury is known with DNA, but it can also block SH-groups and therefore interferes with the repair enzyme system. In this case other mutagenic substances or irradiation can cause irreparable DNA-damage. In our DNA-repair studies we are using synchronous Chlorella culture. For mercury determinations in cells and macromolecules, n-activation analysis is the most sensitive method. Gradient centrifugation in alkaline sucrose is used for DNA repair investigations and berberine sulfate staining to follow the recovery process of cells after irradiation and/or different mercury treatments.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

2.0028, STUDY OF TRACES OF RADIOISOTOPE POLLUTANTS IN THE NORTH SEA AND THE SCHELDT ESTUARY

E. PEETERS, Inst. Royal Des Sciences Nat., *Brussels, Belgium*

During this year, the research will be oriented to the study of trace elements in the waters of the North Sea and in the Scheldt estuary.

This research was conducted to determine dispersion of the radio- elements in the sea environment.

The level of the trace elements will indicate the importance of chemical pollution which is a crucial problem in organic pollutions.

Generally the sequential analysis of phosphates is a very useful indicator of organic pollution and also of the content of nitrites and nitrates.

At the same time, we intend to study the percentage of copper and zinc in the marine organisms localized in a typical coastal biota.

Concerning the analysis of the metallic pollutions in the water, the samples have been taken during the mission of December 1970, January and February 1971 in the North Sea.

The analysis of the phosphates, nitrates and nitrites and also the study of the bacterial pollution is provided for in the present year.

Draggings would be executed for the harvest of marine organisms in the areas where important radioactive pollution has been noted.

During this year an attempt has been made to show the correlation between the bacterial pollution of the sea environment and the chemical factors.

Seawater samples will be analyzed by atomic absorption spectrophotometry for the greater elements or by neutron activation for 12 to 15 elements. Concerning the marine organisms, we shall study the distribution of copper and zinc in the different organs.

Copper and lead will be analysed in molluscs and in the edible fishes of the coast. This analysis will be made first on contemporary samples and afterwards we propose to do comparative work by the study of the samples we have possessed at the Museum for 30 or 40 years.

2.0030, SORPTION AND MOVEMENT OF POLLUTED WATER IN SOIL
J.W. BIGGAR, Univ. of California, School of Agriculture, *Davis, California* 95616

Necessary information linking the reactions between pesticide and soil, and pesticide and plants, to the characteristics of each other, the soil solution environment, temperature and water movement is very spotty and incomplete. Thus this proposal is for a project to obtain a reasonable amount of related information on typical soils and selected pesticides related to fixation and movement. Depending upon the type of soil, organic additive and environment, a number of reactions will determine the extent of movement and persistence in soils. The organic additive may be absorbed by soil, exchanged, absorbed by plants, decomposed into more or less mobile, toxic products, precipitated or leached into ground water, drainage water and streams.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0031, INORGANIC & ORGANIC IMPURITIES OF IRRIGATION WATERS AFFECTING SOIL PROPERTIES AND PLANT GROWTH
L.D. DONEEN, Univ. of California, Agricultural Experiment Sta., *Davis, California* 95616 (CA-D0-WSE-1529-H)

OBJECTIVE: Investigate effects of kinds and concentrations of salts on soil structure and penetration of irrigation waters into soil; effects on plants of materials dissolved in irrigation waters, degree of accumulation of harmful salines in soil as affected by kinds and concentrations of salts in water, soil conditions, climatic conditions, and practices of growers; study of suitability of sewage effluents and drainage waters as irrigation waters.

APPROACH: Two lysimeter studies are under way. One in the greenhouse includes 2 soils and 13 waters of varying quality. The other is a large outdoor installation employing 9 waters of varying quality from which yield can be obtained. These studies are concerned with infiltration rates, salt balance, leaching requirements for chloride and bicarbonate waters and their effect on soil properties. Miscible displacement in being investigated. This is fundamental to understanding simultaneous solute and fluid transfer processes. Both velocity and diffusional mixing are important, as well as the media itself, in determining distribution of solute.

PROGRESS: Laboratory, field, and computer techniques were employed to investigate the processes and conditions controlling the quality of irrigation water, soil solutions drainage and deeply percolating waters. Emphasis was placed on the salt--and nutrient--leaching patterns in newly developing and older irrigated lands. Computer simulation models were developed and tested to predict solubility, ion association, exchange, sorption, and movement of salts and pollutants under in situ laboratory and field conditions.

SUPPORTED BY U.S. Dept. of Agriculture

2.0032, PROGRESSIVE EUTROPHICATION OF LAKE TAHOE
C.R. GOLDMAN, Univ. of California, School of Letters, *Davis, California* 95616

Lake Tahoe is an oligotrophic, high montane lake whose deep blue color and remarkable clarity are due to extremely low mineral content and productivity. Accelerated eutrophication during the last decade threatens to destroy its natural beauty and much of its economic value. Extensive commercial, urban, and recreational development in the lake's basin has disrupted normal soil stabilzation processes and caused extensive erosion of the upland forest ecosystems. This release of suspended particulate matter and dissolved nutrients to the lake on a massive scale has reduced light penetration and promoted the growth of attached and planktonic algae. Photosynthesis in the lake has increased by 72% in the last decade.

The efficiency of natural ecosystems for protecting soil and conserving eutrophication nutrients has already been demonstrated in the eastern United States. This research will determine the quantitative effects of erosion products on Lake Tahoe, assess the relationship between forest and lake nutrient cycles and investigate the potential of both native and exotic plants for revegetation of eroded high altitude areas in the west. Particular attention will be given to evaluating long-term trends in the lake's heat budget as influenced by turbidity from sediment and algal growth.

SUPPORTED BY U.S. National Science Foundation

2.0033, PLANKTON COMMUNITY ECOLOGY IN NORTHERN CALIFORNIA LAKES
C.R. GOLDMAN, Univ. of California, Graduate School, *Davis, California* 95616

This research is concerned with the dynamics of plankton populations in lakes deriving their water and nutrients from coniferous forests in northern California. Important structural parameters will be calculated for both phytoplankton and zooplankton populations. A detailed study of the structure of the plankton communities in Castle Lake will be done using recurrent group analysis. A multiple regression analysis of the plankton population data and the limnological data important to such populations will be performed in order to uncover the functional relationships of the major species of the plankton. Estimates will be made of the amount of energy flowing through the different compartments of the plankton. After these four kinds of data reduction are completed a model of the plankton systems will be developed which takes into account energy accumulation and species interactions for each important plankton population. The project is to be expanded to include work on bacterial energetics, spatial distributions of phytoplankton, benthos and fish, and zooplankton respiration.

SUPPORTED BY U.S. National Science Foundation

2.0034, EUTROPHICATION OF SURFACE WATERS - LAKE TAHOE
P.H. MCGAUHEY, Lake Tahoe Area Council, *El Cerrito, California* 94530

The project is designed to demonstrate what compounds, nutrients, etc. occurring in the effluent from conventional or advanced waste treatment processes or storm water runoff contribute to the eutrophication of surface waters in general, and in Lake Tahoe in particular. Initial studies will be in laboratory-scale growth units with later studies in plant demonstration ponds.

2.0035, COLLISIONS IN WASHOUT
T.G. OWEBERG, T.G. Owe Berg Incorporated, *Garden Grove, California* (AT(04-3)-673)

Experiments are conducted to study the motion of a single particle in the vincinity of a falling single drop, simulating the conditions of washout of atmospheric particles by rain. The trajectory of the particle is determined by high-speed photography. The variables are size, charge, and fall velocity of drop and particle. They are measured for each pair of drop and particle. The particle is charged and suspended in a nonuniform ac field with a superimposed dc field. The drop is charged by induction. The falling drop intercepts a light beam and thereby triggers a relay that disconnects the fields, so that the particle falls freely, and opens the shutter of the camera. In order to make sure that particle and drop center are in a plane parallel to the film of the

high-speed camera, a picture is taken with a still camera at right angle to the optical axis. The collision efficiency can be calculated from particle trajectories that barely miss the drop.

RESULTS: Results have been published in J. Atm. Sci. 27 (1970) pp. 435-442 and Proc. Precipitation Scavenging Meeting, Richland Washington, June 1970. A third paper has been submitted for publication.

2.0036, RADIONUCLIDE METABOLISM IN AQUATIC ANIMALS

F.L. HARRISON, Univ. of California, Lawrence Radiation Laboratory, *Livermore, California* 94551 (W-7405-ENG-48)

The uptake and lose of radionuclides by aquatic organisms are being followed in representative fresh-water and marine organisms consumed by man. Two types of studies are being conducted. The first of these are determinations of the biological turnover of minerals having radionuclides produced in nuclear events. Fresh-water clams, crayfish, and fish and marine clams, crabs and fish are maintained in aquarium systems where the radioactive and stable element concentrations are held constant. Whole body and tissue and organ uptake rates are assessed at different water temperatures and stable element concentrations, in animals of different size, and in fed and starved animals. Loss rates are determined under laboratory conditions and in natural habitats. The second of these studies are assessments of the comparative biological availability to aquatic organisms of radionuclides produced in contained and cratering nuclear explosions. Fresh-water and marine ecosystems are established in aquarium systems or large pools containing water which continuously leaches nuclear debris. The concentrations of fission and activation products are followed in the water, plankton, and animals. Bivalve molluscs, crustaceans and fish are dissected to determine tissue distribution and concentration of activity. Radionuclide analyses are performed on lithium-drifted germanium diode detectors.

Results: Rates of accumulation of radionuclides differed with the animal and radionuclide. They were affected by temperature and stable element concentration and changed with the size of the animal. The loss rates were more rapid in natural habitats than in the laboratory and the elimination of the radionuclides followed two or more component curves. Nuclear debris radionuclides differed in their availability to aquatic organisms. For some radionuclides, the availability was lower for contained than for cratering events. In general, the highest whole body doses to man were calculated for those fractions of the animals containing the visceral organs.

2.0037, MORPHOLOGY AND STABILITY OF STREAM CHANNELS IN SOUTHERN CALIFORNIA

J.B. MURPHEY, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Lompoc, California* 93436 (SWCW2-GLMP-1)

OBJECTIVE: Methods for predicting and control of gully and stream channel erosion, and sediment deposition damage.

APPROACH: Evaluate processes of channel aggradation, degradation, horizontal realignment, and changes in cross-sectional shape and net sediment yield in relation to types of bed and bank materials, upstream sediment sources, streamflow regimes and control measures.

PROGRESS: During the past five years the slope course and cross section surveys of Owl Rock Canyon, a 648 acre watershed near Moorpark, California, seem to indicate that an increase in rainfall over the previous year will cause aggradation in the channels instead of scouring them out further. Conversely, when the seasonal rainfall decreases a degrading of the channels is caused by the lighter runoff. This is probably due to the fact that smaller storms occurred during the last part of the water years which showed a seasonal decrease in total precipitation over the previous year. These late season storms were able to produce some runoff in the channels, thus scouring them out somewhat, but were of insufficient size to introduce very much new sediment into the channels upstream. The temporary wooden 16-inch Broadcrested V-notch Weirs met and withstood a rather supreme test in the form of the '100-year' January 1969 storms. All but one of the weirs were completely topped at least once during the peak stages of runoff, but not one of them shows the slightest structural damage. The only damage of any sort noticed was slight abrasion of the fiberglass surface above the stainless steel sheathing on the Owl Rock Canyon weir.

SUPPORTED BY U.S. Dept. of Agriculture

2.0038, VENTURA CALIFORNIA COOP

H.G. GREENE, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

States to which project pertains: California.

The Ventura project is concerned with the geophysical mapping of the nearshore portion of Ventura Basin near the seaward edge of the Oxnard Plain and the geophysical study of submarine canyons contained within the area. The geophysical survey consisted of marine seismic reflection profiling with a high resolution, 1 KJ sparker, an intermediate penetration, 33 KJ sparker, and magnetic profiling with a marine proton precession magnetometer. Wide angle seismic refraction (sonobuoy) profiles were obtained to give apparent velocities of the subsurface sediments. Continuous vertical temperature-salinity profiles will be made in the submarine canyons during times when the water table is at peak recharge in order to try to distinguish areas where fresh water aquifers may discharge.

The principle objectives of this project are (1) to seismically map geologic structures of a portion of the Ventura basin and the offshore area of Oxnard Plain: to establish geology, its structure and tectonic history; genesis, thickness, and depositional history of the sediments, (2) to determine the distribution and locations of fresh water aquifers, entrance areas of possible salt water encroachment, and to map the overall offshore ground water basin, and (3) to determine the origin of Hueneme, Magu, and other minor submarine canyons in the areas and determine their significance as it relates to the geology of the region.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0039, SOIL ENGINEERING RESEARCH

H.W. OLSEN, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

States to which project pertains: California.

The Soil Engineering Research Project: (1) Contributes to interdisciplinary topical investigations of engineering geologic problems and hazards with original research concerning, and applications of, soil engineering principles and methods. Current emphasis is on the potential hazards associated with the San Francisco Bay sediments; specifically, seismic ground amplification, liquefaction susceptibility of granular deposits, static and seismic stability of slopes and dikes, total and differential settlement from overburden fills, and subsidence from groundwater extraction. (2) Supports regional engineering and environmental geologic studies with (a) determinations of the engineering classification and in situ state properties of unconsolidated earth deposits, (b) correlations of these properties with geologic parameters, and (c) interpretations of their significance for land-use planning and engineering purposes. Current emphasis is on the unconsolidated deposits, hydrothermally altered rocks, and residual soils in the San Francisco Bay region.

2.0040, ORGANIC GEOCHEMISTRY OF SAN FRANCISCO BAY WATERS AND SEDIMENTS

D.H. PETERSON, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

Purpose: To increase our limited knowledge of the factors which control the abundance, distribution, and composition of organic matter in coastal waters and sediment.

Methods: 1) Determine the relative abundance, distribution and clay mineralogy of suspended sediment in San Francisco Bay waters in relation to source and waters, such as the distribution of saline water. 2) Survey the abundance and distribution of organic carbon in San Francisco Bay waters and sediment in relation to

season, source and differences in depositional environment such as the distribution of NO3 and oxygen dissolved in the waters. 3) Study the distribution of specific trace elements in relation to the distribution of organic matter. 4) Survey the distribution of pesticides in sediment in relation to depositional environment and depth in sediment. 5) Study abundance and composition of organic matter thought to be of prime importance in the engineering properties of sediment. 6) Study the composition of selected geochemical constituents with depth in sediment in relation to source and subsequent alteration of organic matter.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0041, WATER QUALITY AND NUTRIENTS, SACRAMENTO-SAN JOAQUIN RIVER SYSTEM
W.D. SILVEY, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

This research is part of the program of water resources investigations conducted by the U.S. Geological Survey in cooperation with the State of California. The total project is to provide the knowledge needed to avoid excess blooms of tidal plankton and undesirable concentrations of dissolved oxygen by determining the relationships between nutrients, tidal plankton, dissolved oxygen, and fish in this estuarian environment. The water quality aspects of the study includes source and concentration of both organic and inorganic constituents in waters in the delta system together with pertinent physical characteristics.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0042, DISPERSION OF HEAT IN STRATIFIED FLOW
J.G. WEIL, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

This study seeks means of predicting the spatial and temporal distribution of warm water flows discharged from power plant cooling systems into natural bodies of water. Previous studies of warm water jets have generally excluded some hydrodynamic factors found in natural situations, such as turbulence and shear in the receiving water. In order to predict thermal patterns in prototype siuations, knowledge must be gained of dispersion patterns in waters with turbulence and shear, and allowance must be made for lateral spread of the stratified warm water layer.

Theoretical and experimental work will be aimed at providing quantitative information for predicting the extent of thermal influence in a natural situation near a power plant. This may be accomplished by study of the dispersion characteristics of warm water discharges in stratified flow.

Laboratory experiments will be done to determine the longitudinal and lateral spread characteristics of a warm water discharge flowing over moving receiving water with turbulence and shear. The character of the plume will be described by the velocity of the warm water front, dilution due to entrainment of underlying water, and stability of the front away from the warm water source. Initial studies will be for uniform flow of receiving waters, but later studies might possible include the case of oscillating flow, which would be typical for estuary power plant sites. Atmospheric heat losses and dispersion after the plume has been vertically well mixed will not be of prime importance.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0043, ALGAE DEGRADATION IN WATERWAYS
P.L. MCCARTY, Stanford University, School of Engineering, *Palo Alto, California* 94305

The aim of this research investigation is to evaluate the rate and extent of decomposition under no-light conditions of heterogeneous algae cultures of various ages and grown in various chemical and physical environments. In addition, the incremental effect of small quantities of light on this degradation rate will be studied. This will be directed towards determining the rate and extent of algae degradation so that the possible translocation of pollution by algae can be better predicted and controlled. The study will be conducted in five phases to ascertain the effects of algae type, water characteristics, aerobic conditions, anaerobic conditions, and temperature on the rates of degradation and oxygen consumption observed.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0044, CHARACTERIZATION OF SOIL NONWETTABILITY AND THE DEVELOPMENT OF CRITERIA FOR THE MOST ECONOMIC TREATMENT OF THESE SOILS
J. LETEY, Univ. of California, School of Agriculture, *Riverside, California* 92502

Soils which repel water and are commonly referred to as nonwettable soils have been reported in many areas of the world. Large percentages of areas burned by forest fires exhibit nonwettable soils. Nonwettable soils can be treated with wetting agents to make them wettable and increase water infiltration.

The proposed research will involve developing criteria to predict the most effective and economic treatment of a nonwettable soil with wetting agent to increase water movement through the soil. The necessary parameters will be measured and predicted water infiltration will be compared with calculated values. The parameters to be measured are: critical surface tension of soil, wetting agent adsorption by soil, wetting agent concentration relationship with solution surface tension, and depth of soil affected.

The release of surfactants by soils as affected by various factors will be investigated to predict the longevity of a surfactant treatment and to provide estimates of possible long-range ground water contamination.

A field survey will be undertaken to gain a better evaluation of the extent of nonwettable soils.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0045, FORTY-YEAR FERTILIZER EFFECTS ON NO3 IN GROUND WATER
P.F. PRATT, Univ. of California, School of Biological Sciences, *Riverside, California* 92502

The project proposes to determine the nitrates and soluble salts in soil samples taken at depth of 0-220 ft. from a long-term fertility trial with citrus. The plots, which were not previously fertilized, were established in 1917 on the experimental farm of the Citrus Research Center and Agricultural Experiment Station, Riverside, California. Because complete records have been kept of all nitrogen added, the plots present a unique opportunity to study the contribution of fertilizers to the nitrate in ground water.

During the first year (Nov. 1, 1968 to Oct. 31, 1969) of the project, samples were taken to a depth of 100 ft. These samples were analyzed for field water content and saved for laboratory analysis. During the second year of the project (Nov. 1, 1969 to Oct. 31, 1970) these samples will be analyzed for nitrate and soluble salts. Samples, which will be used for the determination of nitrates and salts, will be taken from the 100 to 220 ft. depth. Also, we will collect undisturbed cores from various depths to determine their hydraulic conductivities at the water contents found in the field.

2.0046, INFLUENCE OF SUBSURFACE WASTE DISPOSAL SYSTEMS ON RECEIVING WATERS
K.D. KERRI, Sacramento State College, School of Engineering, *Sacramento, California* 95819

Recreational facilities and other rural locations frequently rely on subsurface waste disposal systems. The desirability to live near impoundments in remote regions without wastewater collection systems has attracted numerous developments to meet the leisure demands of society. The objective of this research project is to develop prediction models capable of indicating the influence of existing and proposed sub-surface waste disposal systems on receiving waters. Nutrients contributing to the eutrophication of impoundments will be of primary interest. Factors influencing the nutrient load on impoundments and possibly incorporated in the prediction model include chemical and physical properties of soils, depth to water table, rate of groundwater movement, stage of nutrient cycle, and contributing sources.

2.0049, LEAD POLLUTANTS IN NEAR SHORE MARINE ENVIRONMENTS
T.J. CHOW, Univ. of California, Graduate School, *San Diego, California* 92038

The occurrence of lead in various near-shore marine organisms ranging from plankton to fish will be studied to ascertain whether there is a phylogenic relationship with lead content. Comparable specimens from pelagic regions will be analyzed to compare biological concentration in near-shore and open ocean environments. Studies will be concentrated in California coastal areas and correlated with simultaneous lead analyses from water samples and coastal sediments. Particular attention will be given to areas adjacent to sanitary outfalls. Wherever possible, isotopic ratios will be determined, and analyzed for system variation and possible causes.

SUPPORTED BY U.S. National Science Foundation

2.0050, STUDY OF THE DISTRIBUTION OF RADIONUCLIDES IN THE OCEAN - SUBPROJECT 1 - DETAILED EXPLORATION OF CS-137 AND CS-133 IN THE OCEAN
T.R. FOLSOM, Univ. of California, Graduate School, *San Diego, California* 92038 (AT(04-3)34,Proj.071)

Objectives: Information as to moving, stable subsurface oceanic strata at moderate depths.

Background: Means for wide oceanic survey of Cs-137 have been developed.

Procedures: Relatively large samples of Cs-137 are collected on ferrocyanide granules and normalized by reference to Cs-133 also collected. Summing and two-dimensional gamma spectrometry are used for other fallout nuclides.

Continuation: Further development of two-dimensional gamma analytical procedures, especially for study of Co-60, Ag-110m and Ag- 108m to follow up a recent discovery of their usefulness in tracing Pacific water masses. Further improvement of Cs-133 procedures and survey methods in collaboration with other laboratories. Collections of Cs-137 and Cs-133 across the Pacific.

Results: Hundreds of Cs-137 samples have been analyzed showing characteristics of subsurface layers in the N. Pacific. Very recently, Ag-108m has been used to give absolute dates (within close limits) to a certain subsurface water mass frequented by N. Pacific albacore.

SUPPORTED BY U.S. Atomic Energy Commission

2.0051, STUDY OF THE DISTRIBUTION OF RADIONUCLIDES IN THE OCEAN - FALLOUT DISTRIBUTIONS IN SELECTED MARINE ORGANISMS
T.R. FOLSOM, Univ. of California, Graduate School, *San Diego, California* 92038 (AT(11-1)34-PROJECT)

Objectives: Information as to the behavior of cesium, rubidium, and potassium in the ocean and in certain organisms.

Background: Literature values of cesium concentration by marine organisms are in conflict with our findings. Little is reported as to rubidium in marine organisms. Absolute assays of Cs133 by different institutions have been widely discrepant.

Procedure: Radiocesium is assayed by gamma spectrometry with little or no purification. Nonradioactive cesium traces are assayed by flame after concentration and purifications.

Proposed Continuation: Continued development of sources of very pure reagents for rare-alkali research, particularly AMP manufacture in pure form. Completion of the specialized equipment for further study of cesium and rubidium. A careful resurvey to 300 meters for details of the variation of Cs133. Review the cesium and rubidium concentration buildup factors in larger fish with newer techniques.

Results to date: Near completion of the cesium analyses in Salton Sea biological samples. The results to be reported by David Young in PhD dissertation.

Some data suggests higher concentration ability in vertebrates of higher trophic levels. Absolute assays of Cs133 developed and compared with activation reports.

Part 2 of 2.

2.0052, AIR TRANSPORT OF POLLUTANTS TO THE MARINE ENVIRONMENT
E.D. GOLDBERG, Univ. of California, Graduate School, *San Diego, California* 92038

A study of the sources, routes and fates of man-produced materials introduced to the marine environment through the atmosphere. The initial work involved the chlorinated hydrocarbon pesticides, their degradation products, and their carriers, such as talc, and emphasized (1) the long distances of transport, thousands of kilometers, in such wind system as the monsoons and (2) the winds transported such materials in amounts similar to those carried by major river systems. The areas studied included the Northern Indian Ocean with inputs from Africa, northern India and the Indo-China Peninsula through the monsoons, the Caribbean with inputs from Africa through the Northeast Trades, and the northern Pacific with inputs from the European-Asian arid regions through the jet stream.

Presently, we have identified two other materials that may be entering the marine environment in substantial amounts: mercury and flyash. Methods for the rapid and accurate analyses of chemical species of mercury and of the flyash by chemical and microscopic means respectively has been developed. Analyses of mercury in various components of the marine environment indicate mercury levels in animals of the sea 500 times higher than in comparable volumes of sea water on the average. Already man's impact upon the marine environment can be seen in the dispersion of mercury containing substances in high concentrations about sewer outfalls. Since, most of the dispersion of mercury about the environment appears to take place atmospherically, a program of analyses of various marine airs and surface waters is to be initiated in the spring of 1970.

2.0053, STUDY OF KEY WEST DESALTING PLANT EFFLUENT
J.W. JOY, Westinghouse Electric Corp., *San Diego, California* 92121

The project is concerned with the impact of the effluent from a large desalting plant located in Key West, Florida. The effluent is characterized by elevated temperatures, high salinity and low alkalinity. The following physical measurements have been made at stations distributed over the study area; temperature, salinity, dissolved oxygen and alkalinity. Biological measurements and observations have been made at these stations as well as additional ones. The major objectives of the study have been to trace the extent of the effluent by measuring the physical parameters above and to detect the effects of the effluent on the marine communities in the study area. There has also been some attempt to identify what physical parameters are influencing the biota in the immediate region of the discharge plume.

2. WATER QUALITY

2.0054, TRACE ELEMENTS IN GRAND RIVER AND LAKE ERIE
R.F. PLATFORD, Canadian Cen. for Inland Water, *Burlington, Ontario, Canada*

A study of certain trace elements, including nutrient and toxic elements, their speciation and distribution in the Grand River and in eastern Lake Erie.

SUPPORTED BY Canadian Government - Ottawa

2.0055, AN ASSESSMENT OF RADIOACTIVE FALLOUT
M.T. SHIOMI, Canadian Cen. for Inland Water, *Burlington, Ontario, Canada*

An assessment of the usefulness of a study of radioactive fallout and its application to the study of sedimentation in lakes.

SUPPORTED BY Canadian Government - Ottawa

2.0056, GEOCHEMISTRY-MINERALOGY OF THE MACKENZIE RIVER
A.A. LEVINSON, Univ. of Calgary, *Calgary, Alberta, Canada*

The Mackenize River is the second largest in North America and is virtually unpolluted. Geochemical and related clay mineralogy studies, therefore, could be of fundamental importance in understanding the chemical characteristics of these water and the clay absorption characteristics (of which this is virually no information) but also could be applied to other river systems throughout the world. The major tasks of the project are: 1. determine amount of suspended sediment and type of clay minerals from the major tributaries and the Mackenzie. 2. determine trace and major dissolved elements. 3. determine the extent of the 'salt water wedge' from the Arctic Ocean. 4. clay mineralogy studies of deep-wells now being drilled in the Mackenzie delta. 5. study the geochemistry of boron for understanding of the 'paleosalinity- paleoenvironment problem'. 6. study the clay mineralogy boron and other trace elements in the fresh water deltas entering lake Athabasca.

SUPPORTED BY Amer. Chemical Society - Washington, D.C.

2.0057, THE ROLE OF SLUDGE WORMS IN PROMOTING EUTROPHICATION
R.O. BRINKHURST, Univ. of Toronto, *Toronto, Ontario, Canada*

The study attempts to discover the role of the abundant sludge worms of polluted sediments in promoting eutrophication.

The reclamation of lakes after sewage disposal may be accelerated by the mineralization of sediment and the removal of oxygen demand by the worms, or it may be hindered by the retrieval of otherwise trapped organic matter by them.

The study attempts to elucidate the rate of utilization of organic sludge by worms in a grossly polluted harbour at Toronto and possibly in a series of sites in the trophic gradient of the Bay of Quinte, Lake Ontario.

The study entails research on the types of bacteria present, the types of nutrients present (amino acids, sugars, for example), the relationship between these and the worms, the abundance of the worm species in the harbour, the respiration growth efficiency and feeding rate of worms under various conditions.

The work on most of these sub-programmes has been begun following build-up of staff, equipment and methods. The rate of progress indicates that initial modeling might be contemplated in late 1970, using the theoretical study recently completed.

The project will include consultant services for the identification of sludge worms from Alaska for FWPCA personnel. Similar facilities can be offered to other FWPCA projects and regional offices by arrangement.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.0058, ECOLOGY OF A TROPICAL SHORE - PRE-ANALYSIS FOR POLLUTION STUDIES
P.W. GLYNN, Smithsonian Institution, *Balboa Heights, Canal Zone*

On December 13, 1968, the 35,000 barrell tanker 'Witwater' broke up on a track 2 to 3 miles from the STRI marine laboratory at Galeta Island, inundating the shore line with 20,000 barrels of bunker 'C' and diesel oil. With few exceptions too little quantitative data was available on the biota of the adjacent coral reefs and mangroves to adequately assess the 'biological costs' of oil pollution in this area (i.e., short and long term disturbances to biomass and to biological succession including displacement and/or replacement of particular species).

The STRI proposes through its own staff and assemblage of various outside experts to engage in a program which will lay the basework for evaluating the biological costs of future oil spills on tropical and related ecosystems. The roles of several natural agents of oil pollution abatement will be delineated.

SUPPORTED BY Smithsonian Institution

2.0059, EUTROPHICATION OF PONDS IN SOME NEW MEXICO LAVA BEDS
R.W. PENNAK, Univ. of Colorado, Graduate School, *Boulder, Colorado* 80302

Year-round study of productivity at primary and secondary levels as an interpretation of varying levels of eutrophication in a group of small ponds in a lava flow.

SUPPORTED BY University of Colorado

2.0060, EFFECT OF COPPER SULFATE ON AQUATIC WEEDS
T.R. BARTLEY, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

Laboratory studies and experiments by other investigators have shown that copper has a pronounced effect on higher forms of aquatic vegetation. Copper has been used for many years as an effective algaecide. This study was undertaken to determine the effects of a semicontinuous feed of low concentrations of copper on the growth of aquatic weeds common to Western irrigation canals.

Small copper sulfate crystals are fed into the flowing water at a calculated rate based on water volume by means of an automatic feeding device equipped with a timer. The copper sulfate is fed into the water daily throughout most of the irrigation season. The aquatic weed growth will be observed frequently through the season to determine the effect of the treatment. Concentration of copper in the irrigation water will be monitored. Total alkalinity of water on copper concentrations is being investigated. Water temperature and other factors are investigated in this aquatic weed control study.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0061, SEDIMENT PROCEDURES DEVELOPMENT AND RESERVOIR SEDIMENTATION
W.M. BORLAND, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

Studies to develop or improve the techniques of computing sediment transport in channels; determining stable channels; computing degradation below dams and scour at siphon and bridge crossings; and determining the efficiency and effectiveness of settling basins and sediment control facilities at diversion dams. Existing reservoirs are periodically resurveyed to determine their current area and capacity amounts. Added research value of the surveys include collecting basic data related to watershed unit sediment yield rates; unit weight of deposited sediments; reservoir delta formation patterns; degradation below dams; sediment distribution; and trap efficiencies. Improvement is continually sought in instrumentation techniques and in developing better equipment to conduct the reservoir surveys. Computer programs are being written for specific sediment and hydraulic problems that require iterative processing of the collected field data.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0062, VELOCITIES OF RADIONUCLIDES AT ARMARGOSA SITE
D.B. GROVE, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

The investigations are designed to obtain information concerning: (a) the ground-water system in the carbonate rocks, rhyolites, and tuffs of the Nevada Test Site, (b) the hydraulic properties of earth material and aquifers that need to be considered in predicting the rate transport of radioactive products produced during a nuclear detonation, and (c) the chemical factors affecting the rate of transport of the same products.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0063, LARGE IMPOUNDMENTS - TEMPERATURE PREDICTION IN IMPOUNDMENTS
D.A. HOFFMAN, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

The Bureau of Reclamation has constructed numerous large impoundments which are characterized by being deep and long, located in an arid climate, and relatively unknown from the standpoint of limnological data. The lack of information is perhaps the greatest void in water data on these reservoirs.

Temperature Prediction in Impoundments is a study underway to determine the usefulness of a mathematical model to predict the temperature in large impoundments. Presently, data are being collected on existing impoundments in order to verify and update a mathematical model.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0064, LARGE IMPOUNDMENTS - EUTROPHICATION OF LAS VEGAS BAY, LAKE MEAD
D.A. HOFFMAN, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

The Bureau of Reclamation has constructed numerous large impoundments which are characterized by being deep and long, located in an arid climate, and relatively unknown from the standpoint of limnological data. The lack of information is perhaps the greatest void in water data on these reservoirs.

During the surveys of Lake Mead it was found that the Las Vegas Bay was an area of poor quality water due to the low dissolved oxygen and high dissolved salts. As a result, it became obvious that an extensive study of this reach of Lake Mead should be made. Field studies will be made to quantitatively and qualitatively define, analyze, and recommend solutions needed to improve the water quality in Las Vegas Bay.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0065, ENGINEERING GEOLOGY RECONNAISSANCE STUDIES OF COASTAL COMMUNITIES, ALASKA
R.W. LEMKE, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

State(s) to which the work listed herein pertains: Alaska.

Reconnaissance engineering geology studies, directed principally toward assessing potential earthquake and other geologic hazards, have been completed and open-file reports are being prepared for the following Alaska Coastal towns: Skagway, Haines, Sitka-Mount Edgecumbe, Ketchikan, Metlakatla, Petersburg, Wrangell, Yakutat, Hoonah, Nome, Bethel, Dillingham, Naknek-King Salmon, Unalakleet, Kotzebue, and Barrow. It is concluded that most parts of these towns are built on more stable geologic materials than those beneath towns heavily damaged by the 1964 Alaska earthquake. Nevertheless, in the event of a large earthquake, some communities are susceptible to damage because of amplified shaking in poorly consolidated deposits, slides of rock and snow, ground fissuring, flowing sediments caused by liquefaction, and subsidence due to soil compaction. In addition, harbor areas and other low-lying parts of some towns may be damaged by vertical changes in the land, by seismic sea waves, and by other abnormal waves produced locally by land tilting or by submarine landsliding.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0066, DENVER METROPOLITAN AREA, COLORADO
R.M. LINDVALL, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

States to which project pertains: Colorado.

The project objective is to prepare detailed general-purpose geologic maps of eight quadrangles covering the major part of the Denver metropolitan area. These maps, on a scale of 1:24,000, are designed to provide basic information on the geologic factors pertinent to maximum utilization of land in a rapidly expanding area of urban development. Information to be provided concerns the engineering properties of the surficial and bedrock units, location of potential hazards such as landslides, areas subject to flooding, areas subject to possible earthquake damage, areas of poor foundation conditions, and the location and extent of sand and gravel deposits necessary for construction aggregate materials.

The maps, including a brief descriptive text, are to be released first in open files and subsequently published in the Geologic Quadrangle Map Series. The geologic map of the Arvada quadrangle was released in open files in 1970. A comprehensive geologic report covering all eight quadrangles is planned for the Bulletin Series.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0067, PREDICTION OF MINERAL QUALITY OF RETURN FLOW WATER FROM IRRIGATED LAND
J.T. MALETIC, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

The research is aimed at developing procedures for predicting the mineral quality of irrigation return flows. Such procedures are needed to provide a means for determining the potential impact of new irrigation developments on the water quality of western streams. Related research areas include computer models for simulating the more important chemical reactions in soils that influence mineral water quality, systems analyses studies of water quality in stream segments or basins, influence of surface water storage on water quality, and computer and analog model studies of ground-water patterns.

The research will be conducted on an existing irrigation project. The physical, chemical, hydrologic, and agronomic conditions in the area will be characterized to provide data inputs for: (1) determining the quality of the percolating water, (2) determining the effect of percolating water on drainage effluent, (3) comparing and verifying computer and analog models, and (4) evaluating influences of hydrologic or agronomic changes on the quality of outflow water.

The field work will be performed near Vernal, Utah, on the Vernal Unit, Central Utah Project.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0068, SURFICIAL GEOLOGY OF JUNEAU AND VICINITY URBAN AREA, ALASKA
R.D. MILLER, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

States to which project pertains: Alaska.

The Juneau project started as part of a coastal communities program of earthquake hazard studies following the March 1964 Alaska earthquake. The original primary objective was to investigate and evaluate potential hazards from earthquakes as a result of the geologic setting. The study has been broadened to include other natural geologic events and to try and relate man's use of the land to the existing geologic environmental conditions.

The project consists of differentiating and mapping surficial deposits and performing physical properties tests on selected samples. Development of raised marine and glaciomarine deposits, glaciofluvial, glacial, and lacustrine deposits is coupled to the geologic history, which in part influences the different physical properties inherent in the materials. The availability and utilization of this information can help the planning and execution of urban expansion and industrial development to hopefully avoid geologic pitfalls by taking into account the geologic influence on the environment such as relative stability of deposits in case of severe earthquakes, areas of known or potential rock falls and avalanches, and differing foundation conditions. Geologic mapping will also provide information regarding the available or potential sources of aggregate for construction uses.

A preliminary map with tabular text is being processed for release in open files, and after a final field season the final reports and map will be prepared.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0069, SAN FRANCISCO BAY SEDIMENTS ENGINEERING GEOLOGY STUDIES, CALIFORNIA
D.R. NICHOLS, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

State(s) to which work listed herein pertains: California

1) establish the geology of the fault-bounded bedrock basin; its structure and tectonic history (with Office of Marine Geology); 2) establish the genesis, areal distribution, thickness, composition, physical and chemical parameters, and geologic history of the unconsolidated sediments of the Bay and the bordering areas of present and former marshlands (with Office of Marine Geology); 3) determine the earthquake and other geologic hazards associated with the Bay including the engineering behavior of sediments under static and dynamic loads and the relations of the engineering behavior to geologic parameters (with Engineering Geology Branch) 4) contribute to the geologic history of a significant segment of the San Andreas fault system in support of the earthquake program, and 5) devise, interpret, and present geologic data of significance to regional planning.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0070, GEOLOGIC INVESTIGATIONS, NEVADA TEST SITE
P.P. ORKILD, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

States to which project pertains: Nevada.

The primary objective is to maintain a current synthesis of the geology, geophysics, and hydrology of the Yucca and Frenchman Flat and Pahute Mesa areas at the Nevada Test Site. The investigations consist of: 1. Appraisal of general areas for their test media potential and public safety. 2. Selection and evaluation of specific drill sites as to geologic contacts, geologic media, water table, faults and lineaments. 3. Limited geologic mapping at selected sites. 4. Monitoring and logging of the drill holes. 5. Field studies of both preshot and postshot geologic effects. 6. Synthesis of structural, stratigraphic, chemical and physical property data. 7. Reporting on the geology and test media potential of Nevada Test Site and adjacent areas.

All phases of the investigations are continuing and the results are reported immediately to the responsible agencies. Longer term results, the detailed geologic knowledge, both surface and subsurface, of a typical and most thoroughly probed alluvial valley and volcanic plateau in the Basin and Range Province, will be reported in professional papers in FY 71-72.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0071, GROWTH SUPPRESSION AND REDUCTION IN REGROWTH POTENTIAL OF AQUATIC WEEDS
N.E. OTTO, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

Successful continued control or eradication of rooted submersed aquatic weeds requires information on methods to reduce or eliminate the regrowth potential of the aquatic plant to a point where they produce insignificant problems. Studies have been conducted to gain a better understanding of organism ability to reproduce itself in subsequent growing seasons. These studies include influence of treatment on stage of growth, number and type of herbicide applications necessary to reduce the amount of vegetative growth and propagule development, amount of propagative material produced by a clone of plants and food reserves in the propagule.

Laboratory investigations show that pondweeds treated with repeated aromatic solvent and acrolein applications in one growing season significantly reduced vegetative propagule production. A significant reduction in number and size of propagules was accomplished in successive treatments. Preliminary studies on the development of vegetative propagules of sago pondweed indicate that they commence development with the onset of plant flowering and fruiting. Continuing laboratory and field studies suggest that low rate, long contract period applications of a number of aquatic herbicides show promise on significantly suppressing the growth of rooted aquatic weeds, thus reducing potential residue hazards as well as controlling weed growth.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0072, FIELD INVESTIGATION OF THE SUBMERSED AQUATIC ENVIRONMENT
N.E. OTTO, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

Study of the ecological relationships of plants and animals in canal and reservoir environments are necessary to gain understanding of biological problems existing in these areas. Knowledge of environmental factors and interactions are essential to future improvement of aquatic weed and animal problems existing in irrigation distribution systems. Data have been collected from irrigation canals in three different geographical areas concerning the physical, chemical, and general biological aspects. Samples of soil, water, and biological materials are being collected for chemical and physical analyses in both weed-free and heavily infested canal sites. Observations are being made of all physical, chemical, and biological factors suspected as being important in the environment. Data obtained to date indicate that rooted submersed aquatic weeds are adapted to a wide range of environmental conditions, and no one specific set of factors nor interaction of factors has been demonstrated as being responsible for pondweed invasion and establishment in a canal system. Present emphasis on this phase of the aquatic pest investigations program is associated with more detailed study of the nutrient requirement of submersed aquatic weeds, including filamentous green algae.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0073, SMALL IMPOUNDMENTS - FOSS RESERVOIR
P.R. TRAMUTT, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

In addition to the large reservoirs covered by other studies, the Bureau of Reclamation has many small impoundments which very in their shape, operational mode, and climate from deep canyon reservoirs in mountain locations with a comparative high flow-through rate to shallow reservoirs located in the plains and operated with periods of long holdover. A research program was initiated with Region 5 for a water quality survey in the plains-type Foss Reservoir. The water in Foss Reservoir has been held in storage since March 1961, and the quality has been deteriorating due to an accumulation of dissolved solids. The deterioration has been accentuated by the retention of good quality water in upstream watershed development ponds. This study was scheduled for completion in FY68, but was continued to provide data for the demineralization study conducted during FY69. The revised completion date is FY71. This study will be completed and the data collected in previous years will be published in a short report.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0074, BEHAVIOR OF POLLUTANTS IN WATER
R.L. WERSHAW, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

The objective is to study pesticide residence time, transport mechanisms, and projected residue levels in natural soil and in natural hydrologic environments. The mechanisms of infiltration and solution of certain pesticides are being studied in the laboratory and conjunctive field studies are being planned to obtain information on the parameters related to subsurface infiltration and to the migration, retention, and decomposition in ground and surface waters.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0075, HYDROLOGIC STUDIES LEADING TO SITE UTILIZATION
S. WEST, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

Study the hydrologic regimen around nuclear test areas and supply the knowledge gained to safety and engineering management practices. Provide data for utilization of water resources around nuclear test sites.

Specific major areas of study include: (a) natural hydrochemical and hydrogeologic conditions near sites of planned atomic detonations, (b) distribution of radionuclides in earth materials and associated groundwater, (c) field transport characteristics of radionuclides.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0076, IRRIGATION RETURN FLOW - NUTRIENT BALANCE
R.F. WILSON, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

Flows from irrigation projects have been unduly criticized for the deterioration of the water quality in receiving waters. Much of the salt content of many river basins has been attributed to irrigation projects. Studies based upon the transmission and fate of agricultural chemicals including fertilizers and pesticides will be supported and coordinated with related studies being performed under other Reclamation activities and by other organizations. In order to differentiate the salt contribution from natural irrigation, municipal and industrial sources two catagories have been made under the main heading.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0077, VEGETATIVE STABILIZATION OF MINE TAILINGS, WASTES, AND SPOILS
W.A. BERG, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00020)

OBJECTIVE: To identify problems associated with establishing vegetation on mine tailings, wastes, and spoils. To determine treatments, techniques, and species required to establish and maintain vegetation on tailings, wastes, and spoils. To classify tailings, wastes and spoils by chemical and physical composition, climate, and topographic features in relation to requirements for and feasibility of vegetative stabilization.

APPROACH: Treatments, techniques, and species for revegetation will be determined by a combination of laboratory, greenhouse, and field work. Physical and chemical properties significant to plant growth on the tailings, wastes and spoils will be determined. Greenhouse studies will be used to investigate nutrient deficiencies and toxicities, and for exploratory work on species selection. Field experiments will be used for species selection, establishment techniques, nutrient and toxicity problems, and for determination of maintenance requirements, longevity, and feasibility.

PROGRESS: Studies were made on uranium, molybdenum, and gold tailing and on limestone and uranium spoils. In field studies on Mo tailings at an elevation of 11,000 feet, cereal rye seeded immediately after the snow-pack melted (May 28) made sufficient growth by Sept. to stabilize limed and fertilized tailings. Eight grass species seeded in May made little growth by Sept. Native willow cuttings planted on the Mo tailings had an excellent rate of sprouting and root initiation. However, by Sept. many had died. A possible explanation is that the cuttings were rooting below the zone of lime application (about 6'). Willow cuttings planted on nearby soils had a lower initial sprouting rate, but those that sprouted survived. P fertilization of the Ur tailings at one location increased grass growth several-fold. The P deficiency was unexpected as soil tests (NaHCO(3) extraction) indicated P was adequate. On 3 other Ur tailings plant growth was very poor even with leaching, liming, and adequate N, P and K fertility levels. This may indicate a plant toxicity from chemicals used in ore processing. The only extensive colonization of processed tailings by native vegetation was found on old gold tailings at Victor. Here Elmus triticoides, has partially stabilized 1/4 of 40 acres of tailings.

SUPPORTED BY Colorado State Government

2.0078, FLUXES OF HEAT, MOMENTUM AND TRACERS IN WIND AND WATER TUNNELS
J. GESSLER, Colorado State University, School of Engineering, *Fort Collins, Colorado* 80521 (AT(11-1))

This is a study of basic research on absorption rates of particulate pollutants as it is affected by the action of wind and, in turn the wind-generated waves. Beyond this the investigation will cover the behavior of the pollutant after it has been absorbed by the water, where the wind has a very definite effect on the rate of dispersion.

At present no quantitative knowledge on absorption rate is available, but such information is very essential if the effect of fallout on water purity is to be evaluated. But it is not only the water pollution which is of interest. Of similar importance is the fact that the air, after moving over lakes or the ocean, will have lost considerable amounts of the polluting matter. Finally, one should concern oneself with the question of what happens to the polluting matter after it has reached the water and how it is going to disperse.

SUPPORTED BY U.S. Atomic Energy Commission

2.0079, LAND USE AND WATER QUALITY ON FORESTED MOUNTAIN WATERSHED
J.R. MEIMAN, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00312)

OBJECTIVE: Assess water quality within a forested mountain watershed at varying natural flow, measure the effects of multiple land use management--including road construction, logging, recreational developments and grazing--on water quality.

APPROACH: Water quality determinations including total residue, filtrable and non-filtrable residue, pH turbidity, coliform group bacteria and temperature will be made before, during, and after land management practices.

PROGRESS: Five stream temperature stations were installed in the Little Beaver watershed and continuance records of rate temperature collected during the summer and fall of 1969. Data is currently being analysed.

SUPPORTED BY U.S. Dept. of Agriculture

2.0080, SEDIMENTATION AND CONTAMINATION CRITERIA FOR WATER RESOURCES PLAN AND MANAGEMENT
H.W. SHEN, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00112)

OBJECTIVE: Study the effect of vegetation on flow rates, sediment yield and dispersion of contaminant (attached to soil), during surface runoff in watershed.

APPROACH: Cylinders and other flexible elements will be inserted in laboratory flume to simulate vegetation. Radioactive and fluroescent tracers will be used to study the movement of contaminant material and sediment yield. Analysis will be made from a combination of stochastic and analytical approaches.

PROGRESS: A general stochastic model to describe sediment transport is formulated. This model may apply to meandering streams, etc. Experimentally, we have completed this analysis of resistance to flow due to simulated vegetation. A design criteria has been found. At the present time, we are writing a review of literature report on estimating the magnitude of soil erosion from upslope area. We shall attempt to use optimization method for an engineering guide to design erosion control structure.

SUPPORTED BY Colorado State Government

2.0081, MOVEMENT AND ACCUMULATION OF HARMFUL NUTRIENTS IN SOILS AND WATER
F.G. VIETS, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Fort Collins, Colorado* 87101 (SWCW8-DFC-6)

OBJECTIVE: Determine the contribution of various uses of agricultural land, including livestock feeding, industrial and municipal waste disposal, to nutrient enrichment of surface and subsurface waters, soil properties and productivity; and devise systems of fertilizer and waste management on soils to prevent soil and water pollution.

APPROACH: Laboratory and field studies are conducted to determine the amounts and forms of mineral nutrients, such as nitrogen, phosphorus and potassium; and organic substances that create biological oxygen demand or pollute waters that run off or

percolate through soils used for agricultural livestock feeding or industrial and municipal waste disposal. Effects on the chemical and biological quality of water and the physical and chemical properties of soils and their productivity are determined. Alternative and improved methods of land and waste management on soils to reduce pollution are investigated.

PROGRESS: Laboratory column studies designed to simulate two kinds of cattle feedlot management show marked contrast in the kinds of ground water and air pollution possible. In well-drained soil columns kept moist over a 16-week period, 65% of the total nitrogen in added urine was oxidized to nitrate and leached through or stored in the column, about 10% remained in the soil as ammonium, and 25% was lost as ammonia gas. No denitrification occurred. In soil columns started initially dry, to which urine was added each 4 days to simulate lower stocking rates, no nitrification or leaching occurred, 10% of the total N in the urine remained in the soil as ammonium, and 90% of the nitrogen was lost to the air as ammonia gas. These columns produced nitrate when wetted with water. In the vicinity of large feedlots (80,000), ammonia volatilization and catchment by lake surfaces is significant for eutrophication. Estimates of absorption of ammonia by lake surfaces indicate that from 13 to 65 pounds of nitrogen per acre per year may be contributed, whereas control water surfaces get only 3 to 7 pounds. Absorption is comparatively independent of the time of year. Nitrogen in rainfall is not increased by the proximity of feed yards. Physicochemical studies of the equilibrium between phosphate in solution, the soil, and fertilizer predict that more phosphate will be lost to percolating water the lower the clay.

SUPPORTED BY U.S. Dept. of Agriculture

2.0082, ASSESSMENT & PREVENTION OF EXCESSIVE NUTRIENT ENRICHMENT OF SURFACE & GROUND WATER BY FERTILIZERS

F.G. VIETS, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Fort Collins, Colorado* 87101 (SWC-027-DFC-8)

OBJECTIVE: Assess the extent of excessive nutrient enrichment of surface water by runoff and erosion and accumulation of nitrate in ground waters by deep percolation as affected by kind and amount of fertilizer currently applied for crop and range forage production, and determine if fertilizer recommendations for most efficient crop and range forage production are compatible with pollution control.

APPROACH: Laboratory, lysimeter, and field studies, concerned mainly with nitrogen and phosphate, will be conducted to determine the extent of movement in solution and on sediment in runoff water and leachate as affected by recommended and experimental rates of fertilizer application in relation to crop needs, the availability to aquatic plants of phosphorus and nitrogen adsorbed on or contained in sediment, the extent of denitrification in the deep profile, and absorption of nitrate by deep rooted alfalfa. Effects of burning of crop residues and leaching of nutrients from vegetation onto frozen soils will be investigated.

PROGRESS: Core drilling studies in northeastern Colorado had shown that alfalfa removes practically all of the NO(3)-N from the soil profile to a depth of at least 20 feet. A field study was conducted to determine if alfalfa removes nitrate by simple absorption. N O(3)- was placed at various depths and the forage analyzed periodically. The uptake of tagged nitrate from the 4-foot and 8-foot soil depth was negligible for the first three cuttings. Less than 0.01% of the nitrate placed at 4 feet was absorbed and translocated to the tops. Generally less than 0.2% of the nitrogen in the tops came from the tagged fertilizer. Acid traps located at varying distances from cattle feedlots confirm that ammonia volatilization from cattle feedlots is a significant factor in the nitrogen enrichment of soil and surface water. Acid traps near feedlots absorb as much as twenty times more ammonia than the control sites. Limited data show that snow absorbed 0.05 lb. of NH(3) - N(2) per acre per week in a control area as compared to a maximum of 0.43 lb./acre per week at a site near a large feedlot. Coarse-textured soils may lose more phosphate by runoff than fine- textured soils given the same amounts of phosphate fertilizers according to laboratory research on phosphate in soil solutions.

2.0083, OIL SPILL CONTROL FACILITY

W.A. BOYD, Essex Marine Laboratory Inc., *Essex, Connecticut* 06426

The accidental spillage of some of the petroleum products shipped on the Connecticut River is an ever-present danger. A survey of oil shippers showed that on the average at least two tankers or barges are on the river at any given time. It was found that the facilities presently available for the control of an oil spill are extremely limited.

The requirements for an effective oil spill control system for the Connecticut River were determined on the basis of reports of experience elsewhere. It was recommended that one or more depots be established along the river to house the equipment and that a plan of action for an emergency be developed.

SUPPORTED BY Connecticut State Government

2.0084, ORGANIC DEBRIS ON CONNECTICUT BEACHES AND SHORES

R. BENOIT, General Dynamics Corporation, *Groton, Connecticut* 06340

General field surveys of selected sites are made. The quantity and identity of beach debris present in significant amounts is determined. Water characteristics (temperature, dissolved oxygen, salinity, turbidity) are determined. The origin of the debris is determined if possible. The microbial flora of water, sand, mud, and debris are determined in relation to the mode of decomposition of the debris.

SUPPORTED BY Connecticut State Government

2.0085, NUTRIENT EXCHANGE IN RIVERS AND LAKES

C.R. FRINK, Conn. Agric. Expt. Station, *New Haven, Connecticut* 06504 (CONH00732)

OBJECTIVE: Determine the contribution of nutrient ions to waterways from woodlands, farms, homes, and cities, and its division water, sediments, plants and outflow from a lake.

APPROACH: Monitor water volume and concentration of nutrients entering and leaving impoundments on the Housatonic River.

PROGRESS:

SUPPORTED BY Connecticut State Government

2.0086, PHOSPHORUS IN LAKE SEDIMENTS

R.D. HARTER, Conn. Agric. Expt. Station, *New Haven, Connecticut* 06504 (CONH00411)

OBJECTIVE: Discover the nature of the phosphorus exchange between lake sediment and water by studying self diffusion of P through lake sediment, establishing the effect of temperature on phosphorus equilibrium between sediment and water, determining which fraction of mud phosphorus is exchanging with water, and evaluating the rate of movement of phosphorus from sediment into water across a mud-water interface.

APPROACH: Self diffusion through mud will be determined by constructing a core of bottom mud in small glass tubes. The base of the column, or to the water above the soil, P will be added. Rate of exchange of phosphorus from mud to overlying water will be evaluated by placing lake sediment in large cylinders and slowly renewing distilled water over the mud.

PROGRESS: The sediments of two recent man-made reservoirs, both considered highly eutrophic, were compared with those of a third moderately eutrophic lake created naturally about 10,000 years ago. The P content of the sediments was found to increase dramatically as P concentration increased in the incoming water, confirming predictions from previous laboratory studies of P sorption by sediments. Moreover, the distribution of P amongst the various inorganic fractions was strikingly similar to laboratory predictions: the adsorption maximum for NH(4)F-extractable P was estimated to be 350-450 mu g P/g. sediment, and values observed in the reservoirs were 350-500 mu g P/g. In laboratory stu-

dies, NaOH-extractable P increased sharply as P was added, presumably due to precipitation of iron phosphates. In man-made reservoirs, NaOH-extractable P was 10-fold greater than in the natural lake, although the incoming P concentration was only about twice as great. The implications of these observations of new lakes is not encouraging. The most recent impoundment, only 13 years old, was found to contain twice the sediment P concentration as the natural lake after 10,000 years. 'Galloping eutrophication is apparently more than a catchy phrase.

SUPPORTED BY U.S. Dept. of Agriculture

2.0087, HYDROLOGIC-MINERAL CYCLE INTERACTION IN SMALL UNDISTURBED AND MANIPULATED ECOSYSTEMS

F.H. BORMANN, Yale University, School of Forestry, *New Haven, Connecticut* 06520

Continued experiments with a set of small watersheds is capitalizing on the ecosystem approach and computer simulation studies to examine input-output functions of chemical and biological variables of these forested systems as a whole. Treatments imposed on a catchment may yield an economic return in the form of more water, but additional responses such as alterations of the nitrogen cycle are also under study.

The opportunity to examine an adjacent lake will provide a paleoecology or time framework to the manipulated watershed experiments. Specific studies of nutrient budgets, vegetation, stream-forest interactions, lake and stream limnology, system responses to cutting treatments, and weathering sequences, will contribute to the computer modeling and simulation study.

SUPPORTED BY U.S. National Science Foundation

2.0088, CONTROL OF AQUATIC WEEDS

J.F. AHRENS, Univ. of Connecticut, Agricultural Experiment Sta., *Storrs, Connecticut* 06268 (CONH00607)

Progress: In the late fall of 1967 dichlobenil was applied to an irrigation pond to control aquatic weeds in 1968. Water samples were taken at 1, 2, 3 and 4 months after treatments, frozen and later assayed to determine residual phytotoxicity. Oat seeds were watered with 1/2 or 1 inch of the water samples and root growth was measured. Water samples taken at 1 or 2 months severely injured oats but later samples caused no injury. The pond was essentially weed free during 1968 and the water was used to irrigate container nursery stock. To determine the residual effects of 2,4-D in water, 2,4-D butoxyethanol ester in granular form was applied in 2 farm ponds at 1 and 5 ppm. Water samples were taken at weekly intervals up to 36 days after treatment and will be analyzed for 2,4-D by Amchen Products, Inc.

2.0089, THE QUANTITY & MOVEMENT OF NITRATES IN SOIL WATER IN TWO CONNECTICUT SOILS TREATED WITH HIGH & LOW LEVELS OF INORGANIC NITROGEN FERTILIZER

G.F. GRIFFIN, Univ. of Connecticut, School of Agriculture, *Storrs, Connecticut* 06268

The Connecticut soils, one with a fragipan, will be used to study the distribution of nitrates in soil water (with regard to potential ground water pollution) resulting from applications of inorganic nitrogen fertilizer for silage corn. Vertical and lateral movement of nitrates in soil water will be measured with suction lysimeters installed to depths of one, two (or fragipan depth) and four feet. Soil water samples will be taken from the suction lysimeters weekly except from those at the four-foot depth, where daily samples will be obtained. Soil moisture determinations will be made with a neutron moisture probe whenever samples are taken from the suction lysimeters.

On the upper half of each field a randomized complete block design with four replications will be used. Nitrogen treatments will be plus N (250 lbs. of N/acre) and minus N (no nitrogen). The plusN and minus N treatment plots will be separated from each other by buffer plots. Corn will be grown on all plots. On the lower half of each plot, ryegrass will be grown and suction lysimeters will be installed to permit measurement of the downslope movement of nitrates. Yields of corn and its nitrogen uptake will be determined.

2.0090, RELATIVE POLLUTION STRENGTHS OF UNDILUTED WASTE MATERIALS DISCHARGED IN HOUSEHOLDS AND THE DILUTION WATER USED FOR EACH

R. LAAK, Univ. of Connecticut, School of Engineering, *Storrs, Connecticut* 06268

The proposed research plan involves measuring the weight of commercial products wasted through the plumbing fixtures in households, the dilution water used will also be measured. The individual ingredients wasted such as soap, tissue papers, urine, feces, etc... will be analysed in the laboratory.

The purpose is to gather basic data. The relative strengths, character and importance of each ingredient would be expected to show the potential improvements that could be made in redesign of fixtures and water conservation.

2.0091, WORKSHOP ON EFFECTS OF ATOMIC RADIATION ON OCEANOGRAPHY

A. SEYMOUR, Natl. Academy of Sciences, *Washington, District of Columbia* 20037 (AT(49-7)3005)

In September, 1967 a Workshop on Effects of Atomic Radiation on Oceanograpy was held at Woods Hole, Mass. A report resulting from that Workshop and subsequent deliberations by the Panel on Radioactivity in the Marine Environment of the Committee on Oceanography is now in preliminary publication form. The report, to be entitled Radioactivity in the Marine Environment, will contain sections on: Sources of Radioactivity and their Characteristics; Oceanic Distributions of Radionuclides from Nuclear Explosions; Physical Processes of Water Movement and Mixing; Marine Chemistry; Marine Sediments and Radioactivity; Accumulation and Redistribution of Radionuclides by Marine Organisms; Ecological Interactions of Marine Radioactivity; Radiation Effects: and Evaluation of Human Radiation Exposure.

Results: Publication of the report is planned for this fall.

SUPPORTED BY U.S. Atomic Energy Commission

2.0092, CHEMISTRY OF ATMOSPHERIC PRECIPITATION

D.W. FISHER, U.S. Dept. of the Interior, Geological Survey, *Washington, District of Columbia* 20242

The general objective is to obtain a better understanding of environmental factors that determine the chemical nature of precipitation and to assess the role of precipitation in determining the quality of streams and of ground water.

Sampling networks are in operation in New York - New England, St. Thomas, V. I., and in North Carolina in three distinctly different environments. A specific watershed is being studied in North Carolina to relate precipitation chemistry to terrestrial water quality.

Specific attention is being given to the correlation of the sulfate and nitrate content of precipitation with atmospheric concentrations of sulphur and nitrogen to resolve basic problems on the sources of some important precipitation constituents.

2.0093, DRAINAGE OF PENNSYLVANIA ANTHRACITE MINES

G.H. WOOD, U.S. Dept. of the Interior, Geological Survey, *Washington, District of Columbia* 20242

States to which project pertains: Pennsylvania.

Project is to provide geologic data concerning the structure, stratigraphy, mining, and anthracite resources of specified areas in the Pennsylvania Anthracite region. These areas are chosen by the U.S. Bureau of Mines and the Pennsylvania Bureau of Mines

on the basis of surface and subsurface problems related to mine drainage. The geologic data is to be incorporated with hydrologic data provided by the Water Resources Division into reports recommending or not recommending the specified areas as sites for underground or surface engineering and construction projects whose purposes are to alleviate mine drainage problems. Geologic work directed towards the submittal of reports is undertaken only when project areas are chosen and a request is made.

2.0094, BEHAVIOUR OF RADIONUCLIDES IN MARINE BIOTA IN CONNECTION WITH THEIR ENVIRONMENT
J.K. MIETTINEN, Helsingin Yli. Helsing. Univ., *Helsinki, Finland*

Microbial methylation of mercury and uptake, location and excretion of methylmercury in marine animals, especially fish, are studied in the Mediterranean and the Gulf of Finland using the radioactive isotope Hg- 203. Biological half-times are determined by whole-body counting of individual live animals for several months after introducing the labelled compound as a single dose either orally (by plastic canula into stomach) or by muscular injection or by uptake from water through gills. Retention equation is two- exponential, the slow component usually representing 80-90 % of the dose of methylmercury administered.

Biological half-times of the slow component are mostly quite long, varying from a few hundred days to about 3 years in different species.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

2.0095, HYDROSPHERIC ENRICHMENT OF MERCURY STUDIED BY 203-HG-LABELLED ORGANIC COMPLEXES
J.K. MIETTINEN, Helsingin Yli. Helsing. Univ., *Helsinki, Finland*

Using compounds labelled by the radioisotope (203Hg), intake and excretion of mercury 2 ion and methylmercury as the ionic form CH3Hg plus or as the insoluble protein bound form CH3Hg- protein are studied in fish and molluscs. Effect of dose, temperature and way of administration on the amount and rate of excretion are studied by 'whole body counting' individually marked live animals during several months. Experiments are carried out in collaboration between IAEA laboratory of Marine Radioactivity at Monaco and the field research team of this Department at the Tvarminne Marine biology station of the University of Helsinki.

Excretion rates of 203Hg labelled methyl ethyl and propyl mercury in rainbow trout (Salmo gairdneri) are compared. Methylation of mercury by microorganisms in bottom muds is studied in anaerobic and aerobic conditions.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

2.0096, BRACKISH WATER IRRIGATION IN SOUTHERN FLORIDA FLATWOODS
E.H. STEWART, U.S. Dept. of Agriculture, Plantation Field Laboratory, *Fort Lauderdale, Florida* 33310 (SWC-021-BPL-2)

OBJECTIVE: Determine the effect of brackish water irrigation on salinity of the soil, quality of ground water, hydraulic conductivity and other soil-water properties; the relationship between mineralogical, chemical and physical properties of the soil, soil water movement and retention.

APPROACH: Chemical content of ground water and depth to water table will be related to salinity of soils that are only a few feet above sea level. Effects of salt content of percolating water on hydraulic conductivity and other soil properties related to water control and crop response will be measured on soil with a high water table. The salt content of the rootzone will be periodically measured and related to rainfall.

PROGRESS: Studies in South Dade County, Florida show the salinity level in Perrine marl is related to amount and direction of water movement in a marl soil that lies 2 to 4 feet above mean sea level elevation. The salinity was highest during the dry winter months when water evaporates from the soil surface, and was lowest in the rainy summer when rain water infiltrates into the soil. Water tables fluctuated from slightly above ground level to no more than 2 feet below ground level throughout the year. Rainfall pattern and amount, drainage ditch level and ocean tides all affected the ground water level in the field. Chlorine content of the surface soil was above 200 ppm during the rainy summer months and 800 to 2000 ppm during the drier winter period. There was little fluctuation in the chlorine level of 1400 ppm at 40 cm depth in the soil. The electrical conductivity (EC) of soil- water extract at 20 cm depth of soil varied from 9 mmho/cm after the dry season to 5 mmho/cm at the end of the wet season, while at 40 to 50 cm depth EC was nearly constant throughout the year at 6 mmho/cm. The EC of ground water was constant also at 4.5 mmho/cm. Large amounts of salt were removed readily from the surface soil by leaching laterally through beds with water applied in alternate furrows. This method of salt control could be used effectively during the dry season where crops are grown in ridged rows. Effective leaching of salt by rain water through the soil profile would require pumping large volumes of water to keep the water table at or near sea level elevation.

2.0097, MEASUREMENT OF ELEMENTS DEPOSITED FROM ATMOSPHERE
H.L. BRELAND, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-SL-01382)

OBJECTIVE: Determine the amount of chlorine, fluorine, iodine, and sulfur brought down from the atmosphere in rainfall.

APPROACH: Rainfall will be caught in stainless steel rain gauges and collected in acid-leached jugs. The jugs will be changed monthly and analyzed for the elements in question.

PROGRESS: Rain water samples were collected for analysis with raingauges. Lake and stream samples were also taken at approximately one month intervals. A total of 180 samples were collected and 1630 separate determinations were made. The determinations included Al, Ca, Cu, F, Fe, I, K, Mg, Mn, Na, P and F. Some elements, such as Al and Cu, were too low for detection by the methods used; they will probably not be determined in the future. Values obtained for the lake and stream samples were generally higher than those obtained for rainwater.

SUPPORTED BY Florida State Government - Tallahassee

2.0098, THE CONTRIBUTION OF ORGANIC SOILS AND AGRICULTURE TO EUTROPHICATION IN LAKE APOPKA
C.C. HORTENSTINE, Univ. of Florida, School of Agriculture, *Gainesville, Florida* 32601

It is apparent that Florida lakes are vulnerable to accelerated eutrophication through natural and artificial agents. The subtropical climate provides an ideal environment for 'algal blooms', if and when sufficient amounts of the limiting nutrients, phosphorus and nitrogen, are present. During recent years, the primary artificial agent, man, played a major role in eutrophication of Lake Apopka. However, only meager scientific data are available that delineate the contribution from each of man's numerous activities. In other words, no one can say unequivocally that farming contributes more P and N to the lake's waters than municipal sewage or industrial wastes.

Plots will be installed in old cultivated organic soil and newly drained organic soil on the northern shore of Lake Apopka. Management and cropping will be the same as with commercial vegetable production except that fertilizer applications will vary from none to twice normal amounts. Water samples will be collected periodically from soil moisture tubes, shallow wells, and mole drain outlets and analyzed for orthophosphate, total phosphorous, nitrates, nitrites, ammonia, and total nitrogen. Soil samples will be collected at 6-inch depths down to 2 feet and analyzed for phosphorous and nitrogen. Plant material will be removed and analyzed for phosphorous and nitrogen.

In addition to the plot research, water pumped into the lake from the organic soils will be monitored as to quantity and sampled continuously for chemical analyses. Also, we propose to determine the amount of water exchange between the lake and drainage canals through the dam that separates the organic soils from the lake proper.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0099, NUTRIENT AND WATER INPUTS AND OUTGO FROM THE ORGANIC AND MINERAL SOILS IN THE LAKE APOPKA AREA

C.C. HORTENSTINE, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-SL-01468)

OBJECTIVE: Determine the contribution of fertilizers, pesticides, and soil management practices to eutrophication in Lake Apopka. Also, to study the hydrologic pathways in the Lake Apopka watershed as a basis for using the mineral soils as a disposal area for sewage and citrus processing plant effluent.

APPROACH: Field plots will be established on newly cleared and on older cultivated muckland, fertilized with varying rates of mineral fertilizers, and cropped to appropriate vegetable plants. Plant tissue, soil, and soil solution samples from several soil depths will be analyzed periodically for plant nutrients. The movement of plant nutrients through sandy soils into ground water under selected orange groves will be studied by weekly sampling and analyses of soil and soil solution. The ability of these soils to retain applied phosphorus will be determined. Flow patterns of water through the lake will be determined through the use of fluorescein dye.

PROGRESS: Plots were laid out, fertilized differentially, and planted to spinach on organic soil which has been under cultivation for several years; plots were also laid out on newly drained area and planted to carrots with no fertilization. Soil in the first category had pH 6.15 and contained 1440 ppm Ca, 1990 ppm Mg, 39 ppm P, and 530 ppm K. Soil from the newly drained area had pH 7.0 and contained 2195 ppm Ca, 3565 ppm Mg, 356 ppm P, and 755 ppm K. Nutrients were extracted with 1N NH(4) OAc at pH 4.8. The high pH and high fertility in the latter case indicate that this is probably burned over area. Soil samples, from another section in the same area where the clearing operation is not completed, were collected for comparison to verify this assumption. These samples have not been analyzed. Soil moisture tubes were installed in both experimental areas, but no analytical data are available. The main objective in the current research is to determine the movement of N and P through the organic soil into surface water from previously cultivated and newly cultivated areas. Much of the eutrophication in Lake Apopka is attributed to farming on organic soils along the lake's shore. There are no valid research data to verify this assumption. Data collected under this project will partially serve to prove or disprove the accusation.

SUPPORTED BY U.S. Dept. of Agriculture

2.0100, NUTRIENT & WATER INPUTS & OUTGO FROM THE ORGANIC & MINERAL SOILS IN THE LAKE APOPKA AREA

A.R. OVERMAN, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-AG-01468)

OBJECTIVE: Determine the nature and quantity of nutrient transfer between contingent agricultural areas and Lake Apopka.

APPROACH: Chemical analysis will be performed on the soil and lake waters to analyze the nutrient balance of the lake. Water flow patterns in and around the lake will be studied to evaluate relative inputs and outgo of nutrients. Meteorologic and hydrologic data will be used to estimate evaporation and stream outflow.

PROGRESS: Information is needed on the nutrient inputs to Lake Apopka from organic and from mineral soils. Agriculture has been indicated as a major source of pollution of the lake. Field plots are being established on newly cleared and on older cultivated muckland under different cropping and fertilization practices with drainage ditch arrangements to permit the imposition of several different subirrigation, drainage, and flooding water management systems. Flux of water and nutrients through the muck profile and to and from the canals during drainage and subirrigation periods will be determined from water samples obtained from shallow wells, tension lysimeters, and the canals and from pore pressure -- water content relations by porous cup tensiometer -- piezometer units and calibration data relating water content and unsaturated conductivity, hydraulic head, and saturated conductivity, water content, and tension. Water samples will be obtained at least weekly at 15,30, 60, and 90 centimeter soil depths and will be analyzed for total N, ammonical - N, Nitrate - N, total P, orthophosphate - P, K, Ca, Mg, pH and total soluble salts. Fertilizer treatments will be: no fertilizer, one-half commercial rate, commercial rate, and twice the commercial rate.

SUPPORTED BY U.S. Dept. of Agriculture

2.0101, DEPOSITION OF FINE SEDIMENTS IN TURBULENT FLOWS

E. PARTHENIADES, Univ. of Florida, School of Engineering, *Gainesville, Florida* 32601

The primary general goal of the proposed project is the discovery of the flow parameters which control the initiation, degree and rates of deposition of fine cohesive sediments in turbulent flows, and the derivation of analytical relations between these variables. Recent investigations by the principal investigator and co-workers revealed important conclusive relationships on the effect of bed shear stress on the percentage and rates of deposition of fine sediments. Secondary currents have also been shown to be important.

The experimental investigations will be conducted in special equipment constructed at the Coastal Engineering Laboratory of the University of Florida. Its main components are an annular channel containing the water sediment mixture and an annular ring positioned within the channel and in contact with the water surface. The simultaneous rotation of these components in opposite directions generates a uniform turbulent flow field free of floc disrupting elements. Investigations related to the deposition rates and of the effect of secondary currents on the distribution of boundary shear stress and on the deposition rates, have been scheduled for the near future.

The objectives of the project are related to the control of shoaling in navigable channels and to the pollution in estuaries, caused by the transport and deposition of fine solid waste materials.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0102, PRIMARY PRODUCTION AND DECOMPOSITION IN ESTUARINE WATER

H.D. PUTNAM, Univ. of Florida, School of Engineering, *Gainesville, Florida* 32601

The objective of the proposed research is to contribute to an understanding of the synthesis and decomposition of organic matter by primary producers in an estuarine environment. Studies will be conducted to estimate the productivity of certain red and brown algae which are part of the benthic community in the Waccasassa Estuary. Appropriate methods for measuring fixation of isotopic carbon by attached plants were worked out under grant No. WP-00678-03 which will be completed by this investigator August 31, 1967.

In addition an attempt will be made to define more clearly the limiting factors for primary production in the Waccasassa Estuary. Emphasis will be directed toward the interaction of chemical and biological factors.

Efforts also will be made to follow the decomposition of organic matter under anoxic conditions in esturaine sediments. These studies will be directed mainly toward the characterization of substrates which are involved in methanogenesis. The pool size of volatile fatty acids resulting from the breakdown of algae will be determined and efforts made to establish metabolic turnover rates of these components.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0103, EUTROPHICATION FACTORS IN NORTH CENTRAL FLORIDA LAKES

H.D. PUTNAM, Univ. of Florida, School of Engineering, *Gainesville, Florida* 32601

The project objectives are: (1) to determine the validity of criteria now in use in other areas in measuring trophic levels in shallow, subtropical lakes, and if necessary develop other criteria;

(2) to demonstrate the validity of the mathematical model of eutrophication developed by the application of systems analysis techniques and procedures; (3) to determine the controlling factors in the eutrophication process; (4) to establish guide lines to be used by regulatory agencies in the prevention of surface water deterioration. A small lake in an unhibited drainage basin is to be used as a model for eutrophication and will be separated into control and experimental units by a dike. Nutrients will be fed into the experimental unit at a controlled rate. Changes in parameters will be determined and related to the change in nutrient flux to the unit. The ability of the lake to assimilate nutrients, the rates of recovery after nutrient enrichment ceases, and the possibility of controlling the factors inducing eutrophication will be studied.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0104, VIRAL CONTAMINATION

J.L. RUNNELS, Univ. of Miami, School of Marine Science, *Miami, Florida* 33149

It is proposed that the study of viral contamination of estuarine waters be extended as set forth in the Sea Grant Institutional program. In substance the objectives are to: (1) determine which viruses are stable enough in sea water to survive; (2) determine at what level stable viruses are concentrated in marine animals such as the oyster; (3) develop a technique for detection of stable viruses in the estuary; (4) test water and marine animals of Biscayne Bay for the presence of contaminating viruses. Most of the next year should be spent in extending the number of viruses tested, standardization of techniques, and detection of viruses in the Bay.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0105, NUTRIENT & WATER INPUTS & OUTGO FROM THE ORGANIC & MINERAL SOILS IN THE LAKE APOPKA AREA

R.B. FORBES, Central Fla. Agric. Expt. Sta., *Sanford, Florida* 32771 (FLA-CF-01468)

OBJECTIVE: Determine the effects of pesticides, fertilizers, crops, water management and climate on the inputs and outgo of nutrients and pesticides from the soils in the Lake Apopka area; the hydrologic pathways through Lake Apopka in relation to the nutrient status of the lake; the effects of using the mineral soils of the area for disposal of wastes for abating pollution of surface water.

APPROACH: Field experiments on the muckland adjacent to Lake Apopka for study of effects of cropping, fertilization and water management systems; water sampling sites in mineral soils around lake to determine flow patterns and chemical quality; tracer studies of flow patterns in Lake Apopka; field plot studies in use of sewage plant effluent for irrigation of sandy soils.

PROGRESS: Water quality work formerly reported as nonprojected has been expanded and written into a cooperative project with Soils and Agricultural Engineering Departments of the main station. Field experiments to determine the effects of fertilization and management programs on chemical properties of farm drainage water were begun in the latter part of 1969. Sampling of water in the canals and lake has continued. Little or no DDT has been found in drainage water since June 1968. Higher levels of soluble salts, solids and nutrients in the canals were found over the summer months than during the winter and spring.

SUPPORTED BY U.S. Dept. of Agriculture

2.0106, AN ANOMALOUS OCCURRENCE OF SALINE WATER IN THE FLORIDAN AQUIFER

C.R. SPROUL, State Bur. of Geology, *Tallahassee, Florida* 32302

A small area in which water from the Floridan Aquifer contains in excess of 3000 ppm of chloride and is recorded in Lee County, Florida. The area is about 1/2 mile in width and 2 miles long. Wells in the surrounding area commonly yield water containing less than 1000 ppm of chloride. Preliminary work indicates a positive temperature anomaly congruent with the chloride anomaly. It is planned to utilize electrical gamma ray, cliper, temperature, conductivity and flowmeter borehole logging techniques to locate and identify the source of the saline water in the aquifer in this area.

An evaluation of the application of geophysical logging to specific problems in geohydrology is also planned in conjunction with this study.

SUPPORTED BY Florida State Government - Tallahassee

2.0107, SALINE WATER POLLUTION OF POTABLE WATER SUPPLIES THROUGH DEEP ARTESIAN WELLS

C.R. SPROUL, State Bur. of Geology, *Tallahassee, Florida* 32302

The expansion of urban development into previously agricultural areas is resulting in the abandonment of large numbers of wells formerly used for irrigation. Most of the abandoned wells were drilled from 10 to 50 years ago and were constructed without regard to protection of potable water supplies. The water from these wells commonly contains from 500 to 1000 ppm chloride, and is under sufficient pressure to flow at land surface. Water from these wells intrudes lower head artesion aquifers and water table aquifers which normally contain potable water.

The first phase of this study is to outline the problem areas and to evaluate quantitatively the seriousness of the problem. It is planned to rely heavily upon geophysical well logging in this phase of the study.

Also to be considered are certain legal aspects of this problem, principally the advisability of statutory requirements for the adequate plugging of abandoned wells.

SUPPORTED BY Florida State Government - Tallahassee

2.0108, THE EFFECT OF URBAN LAND DEVELOPMENT ON WATER QUALITY

M.W. ANDERSON, Univ. of South Florida, School of Engineering, *Tampa, Florida* 33620

The efficient management of water resources in a rapidly developing urban area requires concise and quantitative measurements of effects of changing land use. As regions are changed from a natural state to other acceptable levels of population density, changes occur in water runoff both in quantity and quality. Decisions involving both projected land use and water quality management are always made more difficult by the lack of quantitative data upon which to make evaluations.

A parcel of land near the University of South Florida, consisting of approximately 160 acres (presently in a natural state but scheduled to be developed into a medium density populated area), has been selected for a study which will have the following objectives: 1. To establish quantitatively the original state of this land. This will include: (a) An inventory of existing flora and fauna and soil conditions. (b) The quatity of runoff. (c) A complete water balance and energy balance. (d) The magnitudes of each of the water quality parameters in the water runoff. 2. To evaluate at regular intervals the following: (a) Changes in the topography and flora and fauna (b) The quantity and quality of runoff (c) Changes in water balance and energy balance. (d) The magnitude of each of the water quality parameters. 3. To correlate the changes in evapotranspiration, percolation, and runoff as well as the changes in amounts and characteristics of the water quality parameters as the land development proceeds.

The parcel of land chosen for this study is ideally suited to this purpose. Topographically it is an almost complete drainage area. Runoff into the area is largely at one corner of the property where a simple wier will be used to measure the surface input. Rainfall gages placed around the area will help determine the rainfall distribution within the 160 acre tract. A small local lake has existed in equilibrium for many years, thus infiltration rates can be estimated with some degree of accuracy. The outflow for the area is by the way of two small streams which lend themselves to simple wier or outfall methods of obtaining flow measurements. Samples of water taken at the overfall and in the lake will be subjected to standard tests for water quality parameters. Local percolation and transmissibility tests will determine the soil characteristics. Evaporation tests will be conducted us (Text Truncated - Exceeds Capacity)

2.0109, RELATIVE LEACHING RATES OF COMMON NITROGEN CARRIERS FROM SANDY SOILS
D.E. SMITH, Rollins College, Graduate School, *Winter Park, Florida* 32789

Objective: Field and laboratory studies will be aimed at determining the relative leaching rates of various nitrogen carriers from sandy soils surrounding the Winter Park, Florida chain of lakes in an effort to evaluate the role of lawn fertilization in the nitrogen enrichment of the lake water.

Approach: The project will have three aspects: (1) Analysis of storm drain effluent for total available nitrogen; (2) Laboratory determination of nitrogen losses from sterilized soil columns; (3) Tabulation of amounts, frequency of application, and types of fertilizers used by lakefront and proximate landowners. Results of the investigation are expected to increase our understanding of the causes of an acute aquatic weed problem in local lakes.

2.0111, RURAL RUNOFF CONTROL
D.W. HILL, U.S. Dept. of the Interior, Federal Water Quality Admin., *Athens, Georgia* 30601

This research is designed to evaluate the contribution of rural runoff to pesticide and primary nutrient concentrations found in natural watercourses. Many phenomena are being investigated in detail, such as: adsorption mechanisms, degrees of reversibility, thermodynamic parameters, and the nature of the ionic equilibria between the particulate phase and classes of pesticides. More general interrelationships will be studied in the field including such phenomena as types and amounts of agricultural chemicals carried in surface runoff, in solution or adsorbed on different materials in the particulate phase; those that are mobile in interflow, and an estimate of the total amount received in the watercourse from other than surface runoff. An overall computer program will be constructed to incorporate those relationships that appear amenable to calculation. In some cases the findings outlined above will be incorporated in detail whereas other relationships may be grossly simplified in an effort to emphasize those phenomena which are relatively important in contributing to water pollution by rural runoff and to de-emphasize those which are relativcly insignificant. Control recommendations and methodology will result from this research.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0112, THE ARTESIAN SYSTEM IN GEORGIA STRATIGRAPHY AND HYDROLOGY OF THE OCALA
R.E. CARVER, Univ. of Georgia, School of Arts, *Athens, Georgia* 30332

The Ocala limestone is a principal source of water for the south Georgia region whose continued development depends upon the intelligent use of water supplies from this aquifer. The hydrologic and recharge characteristics of the Ocala are not well understood; hence the long range productivity of the reservoir cannot be predicted.

The major objectives of the research are to determine: (1) the lithology and distribution of the Ocala and correlative units, (2) the hydrologic and recharge characteristics of the Ocala and correlative units, and (3) the effects of long term use (last 50 years) on the piezometric surface.

Procedure: All known data regarding the geology, water and well records of the Ocala limestone aquifer will be compiled. In addition, palynological, petrological, lithostratigraphical and biostratigraphical studies of the Ocala limestone from well samples and also from the entire outcrop area within the state of Georgia will yield new data on the three dimensional stratigraphy of this aquifer in both the surface and the subsurface. This knowledge will lay the groundwork for further studies on ascertaining where and how the Ocala derives its recharge and where and how the water moves through the Ocala. These additional data will ultimately enable the pinpointing of sources of pollutants.

2.0113, VARIABLE SOURCE AREA RUNOFF
J.D. HEWLETT, Univ. of Georgia, Agricultural Experiment Sta., *Athens, Georgia* 30601 (GEO-03-0328)

OBJECTIVE: Determine the source and path of travel of storm and base flows from a forested basin.

APPROACH: A 60-acre forested catchment at Whitehall, Georgia will be gauged and operated as an observation watershed to describe behavior of water on and in soil. Primary measurements will be streamflow, rainfall, soil moisture, ground water and soil physical properties. Flow will be calculated and expressed in various ways in order to relate volumes of water to source areas and also to rate response of this catchment to others in Piedmont province. Organic and inorganic solutes and sediments will be measured and an attempt will be made to relate these to source of water flows. Results will be used to support and clarify some new concepts of streamflow as generated by variable source areas and unsaturated flow, rather than by surface runoff and groundwater only.

PROGRESS: One PhD student, one Technician and two staff members continued collection and analysis of hydrologic data on the only fully forested study watershed in the southeastern Piedmont province from Virginia to Mississippi. Dr. Wilhelm Tischendorf received his PhD degree on the basis of the thesis listed below. The findings of the study were incorporated into a final report to the Office of Water Resources Research and some portions of the findings were written into a new 'Outline of Forest Hydrology'. The gaging network continues for another 3 years under revised objectives as a cooperative effort between the School of Forest Resources, the Zoology Department, the Georgia Forest Research Council and the State Agricultural Experiment Station. The work to the end of 1969 has shown among other things that drastic revision of traditional surface and subsurface hydrology is necessary to meet the need for new understanding and control of the source, timing and pathway of water delivery from upland areas. In addition some new values for the organic and inorganic detritus production from the first order, forested, Piedmont stream have been secured.

SUPPORTED BY Georgia State Government

2.0114, INVESTIGATION OF THE INFLUENCE OF VALENCE STATES OF IRON AND MANGANESE UPON THE BIOTA OF THE HYPOLIMNION
J.J. HEISE, Georgia Inst. of Technology, School of Biological Sciences, *Atlanta, Georgia* 30332

The proposed research will investigate the role of valence changes in manganese and iron cations and the resulting effectiveness of their utilization by micro-organisms of the hypolimnion. The study will investigate both the absorption of these cations in sediments and the factors which make them soluble for use by biota. Model systems will be formulated from the data obtained to predict the dynamic changes in reservoirs brought about by changes in valence states of cations that affect the biota. Additionally, optimal conditions for high quality water sources may be determined from the data.

Field work will involve the sampling of biota, water, and sediments of selected reservoirs. In the laboratory, the samples will be analyzed, quantitatively and qualitatively simultaneously, for certain valence states of manganese and iron by electron spin resonance spectrometry; a secondary colorimetric technique will be used to determine the total quantities of cations for comparison with valence states found; data will be evaluated to determine changes in the cations as they exist in solution, in micro-organisms, and in sediment.

2. WATER QUALITY

2.0115, A STUDY OF THE EFFECTS OF ISLAND DEVELOPMENT ON LAKE WATER QUALITY
M.A. MCCLANAHAN, Georgia Inst. of Technology, Environmental Resources Center, *Atlanta, Georgia* 30332

Studies of Lake Lanier, a man-made lake on the Chattahoochee River about 35 miles north of Atlanta, Georgia, are being conducted to define water quality and trophic state of the lake in the vicinity of islands undergoing development, largely for recreational purposes. It is intended to establish present conditions in the lake, particularly in the vicinity of the islands. Analyses will include NH3,NO3,PO4, Fe, Mn, and other trace elements as they seem desirable, suspended solids, and light transmittance. Evaluation of the trophic state of the lake in the vicinity of the islands will be based upon routine determinations of temperature, pH and oxygen profiles, secchi disk readings, light transmission and chlorophyll a. Analyses of plankton populations and productivity will be undertaken on occasion during the study period. Studies will be undertaken periodically during and after development in order to define the effects of development on water quality.

2.0116, TOXAPHENE CONTAMINATION - ESTUARINE ECOLOGY
R.J. REIMOLD, Univ. of Georgia, Marine Institute, *Sapelo Island, Georgia* 31327

Recent pilot studies conducted by the University of Georgia Marine Institute revealed a potential pollution problem related to the release of toxaphene into estuarine waters and sediments. The data revealed toxaphene concentrations of approximately 1.07 ppm in the estuarine water and 4,700 ppm in sediments about one-quarter mile from the effluent outfall. The research work is designed to consider the extent (quantity and quality) of this work contaminant in the sediments, water and biota. Attention also is focused on the concentration process in the sediments and its potential relationship to biological and geochemical processes. Concern is also directed to the toxaphene concentration in the estuarine sediments related to biological or chemical degradation. Studies are also being conducted to look at the transportation of the contaminant through the estuaries, and methods of rendering the existing effluent and sediments nontoxic.

Field studies focus on the randomly selected collection sites in the potentially contaminated area compared with samples collected from an undisturbed and thoroughly studied salt marsh watershed adjacent to Sapelo Island, Georgia. This newly discovered site of pesticide concentration within the estuarine ecosystem will become a problem of great public concern with time. The research considered herein will attempt to identify the significance of toxaphene contamination in the total estuarine ecosystem and its potential roles of limitation of seafood production as well as changes induced on the estuary due to its potential toxic effects.

2.0118, POLLUTION IN HAWAIIAN WATERSHEDS
R.H. YOUNG, Univ. of Hawaii, Water Resources Research Ctr., *Honolulu, Hawaii* 96822

Insufficient data is available on the pollution load contributions introduced into drainage channels and streams from agricultural, domestic, and industrial sources. However, some recent studies have identified these as a principal source of contamination of Hawaiian coastal waters. A three-phase study to investigate pollution effects on the water quality of watershed drainage on channels and streams of the island of Oahu and to determine the influence of these waters on the quality of Hawaiian coastal waters has been proposed.

The initial phase would concentrate on a single watershed receiving industrial pollutants as well as surface drainage. The sources of pollution will be identified and their individual contributions to the pollutant load wil be determined. Parameters of biological and chemical quality will be monitored including bacterial indicators, gross organic load, nutrients, planktonic mass, and benthic organisms. These quality characteristics will be evaluated in relation to land use, stream flow, and impact on the coastal receiving water environment.

2.0119, BIOLOGICAL PRODUCTIVITY OF THE COEUR D'ALENE RIVER AS RELATED TO WATER QUALITY
F.W. RABE, Univ. of Idaho, Water Resources Research Inst., *Moscow, Idaho* 83843

The objectives of this study are (1) to collect and analyze certain physical and chemical data from the South Fork and North Fork of the Coeur d'Alene River, Idaho; (2) to measure primary production in various zones of the river and to estimate standing crop of herbivore and carnivore levels over a yearly period; and (3) to determine the median tolerance limits (tlm) of rainbow trout, Salmo gairdneri, to various concentrations and combinations of heavy metals from the river. Field collections will consist of collecting data from various locations in the river which typify clean water and water treated with mine wastes and domestic sewage. Periphyton will be collected to assess production. Laboratory studies will involve bioassays of fish under both static and running water conditions.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0120, CHEMICAL AND BIOLOGICAL CONSTITUENTS IN NORTHWEST WATERS AND SOILS AS RELATED TO IRRIGATION
D.L. CARTER, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Twin Falls, Idaho* 83341 (SWCW8-FTF-18)

OBJECTIVE: Evaluate interrelationship of fertilization and irrigation on chemical and biological constituents in water and soil. Determine the relative chemical and biological constituent concentrations in inflow and outflow waters for irrigated lands. Determine the effects of chemical constituents in water on biological activity and dissolved oxygen.

APPROACH: Measure the quantity and the chemical and biological constituents of inflow and surface and subsurface outflow waters for selected irrigation districts and determine concentration or dilution of these constituents as water passes through soil and underground aquifers. The contribution of agricultural land fertilization to the nitrogen and phosphorus concentrations in outflow water and subsequent effects of downstream water use is evaluated. The effects of varying chemical constituent concentrations and temperature of water on biological activity are determined.

PROGRESS: Two-week sampling of diverted and drainage waters associated with 202,000 acres of land irrigated by the Twin Falls Canal Company indicates that irrigation decreases PO(4)-P pollution. The PO(4)-P in water used by evapotranspiration remains in the soil, accounting for about one-fourth of the PO(4)-P in the diverted water. As water passes through the soil and becomes drainage water, 70 to 90 percent of the PO(4)-P it contained is lost in the soil. Drainage water contains several times more NO(3)-N than does the diverted water but maximum concentrations reached only 4 ppm. This concentration difference results from greater concentrations of Cl , HCO(3), SO(4) S, NA , Ca , and Mg in the drainage waters. In this system waters from the subsurface drains and tunnels are constant temperature at

about 13.5 C and this water enters surface drains carrying surface runoff, thus cooling the total flow to well below maximum quality standard temperatures.

SUPPORTED BY U.S. Dept. of Agriculture

2.0121, CHEMICAL AND BIOLOGICAL CONSTITUENTS IN NORTHWEST WATERS AS AFFECTED BY IRRIGATION
D.L. CARTER, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Twin Falls, Idaho* 83341 (SWC-027-FTF-8)

OBJECTIVE: Evaluate interrelationship of fertilization and irrigation on chemical and biological constituents in water and soil and determine amounts of chemical constituents in return flows from irrigation.

APPROACH: Measure water quantity, temperature, and chemical and biologic constituents of inflow and surface and subsurface outflow waters for irrigation districts and determine concentration or dilution of these constituents as water passes through soil and underground aquifers. Measure nitrogen and phosphorus concentrations in outflow water and relate to fertilizer practices. Measure and evaluate seasonal fluctuations in nitrogen, phosphorus, and total salt concentrations and temperature of surface and subsurface drainage water. Measure effects of water quality on biological activity.

PROGRESS: Irrigation water passing through the soil of a 202,700- acre irrigation tract lost 65% of its initial PO(4)-P and 24 lbs of K per acre per year. There was a net output of 1 ton of soluble salt and 30 lbs of NO(3)-N per acre per year from the same system. These outputs of soluble salt and nitrate contribute to downstream pollution. The salt was assumed to be solubilized from soil minerals, but the source of the nitrate-nitrogen is not known. The diverted irrigation water was heavily polluted from upstream sources, but bacterial counts were very low in subsurface drainage water coming from the irrigation tract. Although surface drainage water contained more organisms than the subsurface drainage water, there was an estimated 56% fewer organisms in the combined drainage waters than in the diverted irrigation water. The water temperature was lowered 3 to 5 C as the water flowed across the surface of the irrigated field.

SUPPORTED BY U.S. Dept. of Agriculture

2.0122, ATMOSPHERIC CHEMISTRY
D.F. GATZ, Argonne National Laboratory, *Argonne, Illinois* 60439 (2-31-109-ENG-38)

The purpose of this study is to improve our ability to estimate wet deposition through a better understanding of (1) rain scavenging processes and (2) the precipitation processes and storm structure that form the basic framework in which the scavenging occurs. The approach is to relate contaminant element concentrations in rain and snow to concentrations in air for various precipitation parameters and aerosol sizes. Measurements of 20-40 elements are made by neutron activation analysis and other techniques on aerosol samples (collected on filters and size-specific impactor stages) and rain samples (both time- distributed and integrated over entire storms).

The measurements will be made at Argonne and also in two cooperative field research programs with other research groups. In Project ITREX (Illinois Tracer Experiment) sequential rain samples will be collected at three locations 1-2 miles apart near Clinton, Illinois. One filter sampler will collect aerosols on a daily basis. A second field study is now being planned to study urban effects on precipitation at St. Louis, Missouri. Aerosol and rainwater sampling is planned at 3- 5 ground-level stations and by aircraft near cloud base.

Results: Three sequential rain samplers have been built and are now operational. A few rain samples have been collected and analysed as part of a program to develop standard sampling and sample handling procedures.

SUPPORTED BY U.S. Atomic Energy Commission

2.0123, STUDY OF CAUSES AND CONTROL OF GROUND WATER INFILTRATION INTO SEWERS
A.T. BROKAW, Amer. Public Works Assn., *Chicago, Illinois* 60637

The purpose of the study is to investigate and determine the current situation relating to the technical, economic and social aspects of infiltration of extraneous waters into sanitary, storm or combined sewers. The investigation will consider all types of extraneous inflow of ground water and surface water into various sewerage systems. This study will be performed by means of a coordinated program of interviews and questionnaires with officials of local government agencies, consulting engineers, construction firms and manufacturers. A detailed investigation of about 24 selected communities or regions throughout the United States and Canada will be conducted. A major result of the study will be the preparation of a manual of recommended practice based on existing technology relating to control or prevention of infiltration. This manual will cover the design and construction practices, maintenance procedures, and regulatory practices. The study was started in June 1969 and should be completed by October of 1970.

2.0124, SCAVENGING STUDY OF SNOW AND ICE CRYSTALS
M.R. JACKSON, I I T Research Institute, *Chicago, Illinois* 60616 (AT(11-1)-578,)

Objective - To study the efficiency with which snow and ice crystals scavenge suspended atmospheric debris in below-cloud sedimentation. Scientific Background for Study - The capture of airborne particulate matter by natural precipitation is very important in the removal of industrial pollutants, biological organisms and radioactive fallout. Recognition that precipitation removes trace materials from the atmosphere is widespread, but little is known about specific collection mechanisms and scavenging efficiency of precipitating rain or snow.

Most of the studies dealing with atmospheric washout have been concerned with the scavenging action of rain. Limited studies have been performed by Engelmann and Perkins, Reiter and Carnuth, Itagaki et al, Vittori et al. Experimental study of simulated crystals has been performed by Starr and Starr and Mason.

Proposed Procedure - A test chamber 1m x 1m x 2.6m high has been constructed. In operation the test aerosol is generated within the chamber, crystals are allowed to fall into the chamber through a trap door and are collected at the bottom of the chamber. The scavenged material is studied for number and location of particles.

Test Objects and Agents - 3.4mu florescent dye particles, 1mu B. Subtilis spores, 0.56 and 0.28mu latex particles and 0.1mu sodium chloride particles have been scavenged by snow and ice crystals.

Results: Experimental investigation of scavenging of particles ranging in size from 3.4mu to 0.1mu has shown that snow and ice crystals have a higher efficiency than raindrops of the same size. It has further been shown that the scavenging efficiency shows a minimum value for scavenged particles having sizes between 0.3 and 0.4mu. It has also been shown that the scavenging efficiency of a snow flake increase as its diameter decreases.

2.0125, ACCUMULATION OF METALS IN THE AQUATIC FOOD CHAIN IN THE ILLINOIS RIVER
B.J. MATHIS, Bradley University, Graduate School, *Peoria, Illinois* 61606

The purpose of this study is to determine the effect of selected metals in reducing the biotic diversity of the Illinois River.

Atomic absorption spectrophotometry will be used to determine the concentrations of selected metals in the water mud, and biota of the Illinois River. Concentrations of metals in water, mud, and biota in non-polluted streams near Peoria, Illinois will also be determined and compared with those found in the Illinois River. Selected species of fishes and benthic macroinvertebrates from unpolluted streams will be utilized as bioassay organisms.

2.0126, PREPARATION AND EVALUATION OF STARCH DERIVATIVES FOR DETERGENT BUILDERS
C.L. MEHLTRETTER U.S. Dept. of Agriculture, Northern Utilization Res. Div., *Peoria, Illinois* 61604 (N1-1-323)

OBJECTIVE: Prepare starch and dextrose derivatives containing a variety of functional groups, and evaluate the products as chelating agents for calcium ions for possible use as detergent builders.

APPROACH: Starch and dextrose will be reacted with such reagents as oxidants, ammonia, amines, thiols, and nitriles to produce a variety of derivatives containing amino, thio, carboxyl and related functional groups. Also, copolymers of starch with vinyl monomers will be chemically modified with such reagents as unsaturated acids copolymerized with maleic anhydride. The products will be tested for chelation of calcium, magnesium, and iron ions as an indication of utility for use as detergent builders. Promising products will be further evaluated for builder performance in household detergents under various conditions of pH, temperature, and concentration. Ability to support algae growth will be studied from the standpoint of stream pollution.

PROGRESS: Procedures were investigated for more economical preparation of carboxymethyl starch and dicarboxyl starch derivatives. A chemical synthesis of dialdehyde starch was developed, and both sodium chlorite and bromine oxidations of dialdehyde starch to dicarboxyl starch were carried out. Dicarboxyl starches of different carboxyl contents and molecular sizes were synthesized. Carboxymethyl starches of various degrees of substitution and molecular weights were also prepared by relatively simple methods for builder study. Evaluation of the products for builder action was delayed, however, by the unavailability of more Foster D. Snell standard soiled cotton. Another standard was purchased (ACH Fiber Service) which required repetition of the detergency tests with the more effective starch derivatives. Five- day BOD evaluations of the carboxylated starches showed that such derivatization greatly reduced the biological degradation of the starch molecule.

SUPPORTED BY U.S. Dept. of Agriculture

2.0127, FATE OF AQUATIC HERBICIDES IN THE AQUATIC ENVIRONMENT
R.C. HILTIBRAN, State Natural History Survey, *Urbana, Illinois* 61801

The proposed research will investigate the fate of the aquatic herbicides, diquat and endothall, after their introduction in the aquatic environment for the control of specific plant pests.

The toxicity of aquatic herbicides to aquatic plants and fishes has been documented. It has been recognized that aquatic herbicides may adversely affect other aquatic biota, but this has not been as well documented.

Data concerning the persistence of aquatic herbicides in water and their removal from water is accumulating. The research proposed is directed to the point: can aquatic herbicides be used in potable water, where their use may be necessary, and not constitute a potential hazard to people using the water? If so, what herbicides can be used and under what conditions?

The length of time the herbicides can be detected in water will be estimated. How are the herbicides removed from the water? Are the herbicides taken up by the fishes and aquatic biota, and to what extent? What are the interactions of the herbicides with the aquatic environment? Can the aquatic herbicides gain access to food utilized by humans? Data from the proposed research will permit a greater understanding of the questions raised.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0128, ALGAL GROWTH POTENTIAL OF ILLINOIS WATERS
R.L. EVANS, State Water Survey, *Urbana, Illinois* 61801

The objective of the study is to develop the methodology that will permit the use of algal growth potential (AGP) as a meaningful index of water quality. Methods for expressing productivity will also be investigated. Sensitivity, reproducibility, and minimum detectability are the major factors to be examined. After methodology and optimum environmental conditions have been established, a general survey of Illinois water will commence. Preliminary results should permit tentative classification of the waters based upon their potential for algal growth. The final phase of the study will relate to the applicability of bench observation to field experience. Currently the most practical expression for productivity would appear to be rate of growth in terms of weight.

SUPPORTED BY Illinois State Government - Springfield

2.0129, DISPERSION AND HEAT DECAY OF THERMAL DISCHARGES
V. KOTHANDARAMAN, State Water Survey, *Urbana, Illinois* 61801

A study has been undertaken to investigate the patterns of dispersion and heat decay of rejected heat discharged into the Illinois River by a power generating plant. A model will be developed to establish the relationship between river water temperature and dry bulb air temperature. This will provide the information for predicting natural river water temperature changes as reference for better delineating the temperature effects of waste heat additions. The patterns of dispersion and heat decay will be monitored in-stream, with corresponding measurements of pertinent atmospheric and flow conditions.

2.0130, NITRATE IN SURFACE WATERS IN ILLINOIS
T.E. LARSON, State Water Survey, *Urbana, Illinois* 61801

Periodic analyses are being made for NO3 on samples from streams in Illinois. These have clearly shown that this ingredient is increasing in concentration over the past 20 years. Intensive sampling of farm drain tiles is being conducted at several small watersheds to correlate with the fertilizer application over the past 5 or more years, and with the soil types, NO3 in streams, and factors influencing its presence in tile drainage.

SUPPORTED BY Illinois State Government - Springfield

2.0131, FATE OF TRACE METALS DERIVED FROM POLLUTION SOURCES IN LAKE MICHIGAN
H.V. LELAND, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

In the proposed investigation the accumulation of lead from pollution sources will be examined in water, sediments and biota of Lake Michigan and several of its major tributaries. In addition, a search will be made for other trace elements that have accumulated in the sediments. Particular attention will be focused on the geographical distribution and amounts of trace metals in the sediments of southern Lake Michigan, the factors affecting sedimentation and distribution of trace metals in the basin, and the concentrating capacity of aquatic animals for lead. The extent of dispersal of trace metals from atmospheric and surface water sources will be determined. Analysis of lead transport from pollution source to adsorption by lake sediments will be conducted.

SUPPORTED BY University of Illinois

2.0132, DISTRIBUTION AND METABOLIC FATE OF INDUSTRIAL POLLUTANTS AND PESTICIDES IN A MODEL AQUATIC ECOSYSTEM
R.L. METCALF, Univ. of Illinois, School of Arts, *Urbana, Illinois* 61801

Little is known about the environmental fate, biodegradability, and ecological magnification of the thousands of organic micropollutants entering the environment as industrial wastes, pesticides, detergents, etc. A simple model ecosystem with a seven element food chain is used to evaluate these properties for micropollutants of any type by introducing a radiotracer preparation of the compound into the ecosystem, allowing it to cycle into the food chains, and assaying the magnitude and nature of the radiolabeled products by thin layer chromotography, radioautog-

raphy, scintillation counting, etc. As a result of the total appraisal each micropollutant can be rated for the degree of hazard that it poses as an aquatic environmental pollutant. It is proposed that the method may be of value as a standard system for judging the suitability of proposed new pesticides and industrial chemicals for uses that may affect water quality and lead to the establishment of criteria and standards for permissible chemical contamination of raw water supplies. In addition, the method will provide data leading to the preparation of a catalogue of ecosystem biodegradability in which specific types of organic compounds, including ring systems and substituent groups, can be characterized for their relative biodegradability and capacity for ecological magnification.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0133, RAINOUT OF RADIOACTIVITY IN ILLINOIS
R.G. SEMONIN, Univ. of Illinois, State Water Survey Division, *Urbana, Illinois* 61802 (AT(11-1)-1199)

Field measurements of tracer chemicals introduced into storm systems, the meteorological evaluation of their motion in the storms, and laboratory experiments on raindrop collection efficiencies of sub- micron aerosol are proposed.

A field experiment in cooperation with the Argonne National Laboratory, the University of Chicago, and the University of Wyoming is proposed whereby tracer materials will be released into clouds to study the precipitation scavenging processes. The clouds will be monitored by aircraft, radar, and ground observations. The rainwater from nearly 75 collectors within a 30 by 30 mile area and from time-resolved samplers in the vicinity of St. Louis, Mo. will be collected to determine the distribution of the tracer and other elements related to the urban environment. The results from this experiment will be used to infer the internal motions of the storm and the effects of urbanization upon the precipitation formation.

Current laboratory experiments will be continued on the measurement of raindrop sub-micron aerosol collection efficiencies with emphasis on the role of the electrical characteristics in the scavenging process. These results will eventually be used as part of a cloud model depicting the removal of aerosols by the precipitation process.

Results: Six storm situations were treated with chemicals during 15 May to 30 June, 1970. The chemical analysis of the rainwater for sodium, magnesium, potassium, and lithium (tracer) has been completed and maps of the deposition over a 400-square mile area have been prepared. The detailed analysis of the storm structure is in progress. The scavenging efficiency of raindrops in the size interval from 0.2- to 5.0-mm diameter for B. subtilus spores as a function of drop charge has been completed.

SUPPORTED BY U.S. Atomic Energy Commission

2.0134, ROLE OF FERTILIZERS IN WATER POLLUTION
L.F. WELCH, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-15-0351)

OBJECTIVE: Determine inorganic ions, principally nitrate and phosphorus, in sub-surface drainage water from agricultural fields and relate the findings to past and present fertilizer and cropping practices.

APPROACH: This study is to be limited initially to concern with drainage water that becomes surface water near the place where leaching occurs and will be related only to commercial fertilizers. It is recognized, however, that this study may be broadened to include the deeper leaching which becomes part of the water table and may later include other pollutant sources such as feed lots, herbicides, insecticides, etc. Primary concern will be for nitrate and phosphorus in drainage water but some attention will be given to cations that accompany them. Five to ten sites (2 to 160 acres) will be selected so that cropping and fertilization can be defined for each. Tile drainage water will be sampled at least twice each week when water is being discharged. Samples will be analyzed for nitrate and phosphorus, and other elements such as potassium, calcium, and magnesium. Volume of flow will be determined at time samples are collected. Results will be related to cropping and fertilization practices.

PROGRESS: Nitrate concentration in water of four drainage ditches was much less in July than in April. The decrease is probably due to removal of nitrate from the water due to absorption by plants growing in the ditches in July. Also, water in the ditch in July had drained from a lower depth in the soil profile than in April. There was a large variation in nitrate content of tile water from farmers' fields. One tile averaged 3.6 ppm NO(3)-N while another averaged 13.5 ppm. The field drained by the low tile has received a low rate of N fertilizer. Concentration of nitrate was essentially independent of flow rate for a given tile. For example, after a rainy period the flow rate may have increased eight fold, but the nitrate concentration often changed very little if any.

2.0136, RADIOACTIVITY IN THE AQUATIC ENVIRONMENT (PART OF A COORDINATED PROGRAMME OF RESEARCH IN MARINE RADIOACTIVITY STUDIES)
A.K. GANGULY, Bhabha Atomic Research Centre, *Bombay, Mahrashtra, India*

The project is research cum monitoring orientated especially to study the cycling and distribution of radioactivity in marine matrices - benthic communities, sediment and sea water - off the west coast of India, with particular reference to Bombay Harbour Bay (18 degrees 55'N and 72 degrees 50'E) which receives radioactivity through the nuclear operations and Tarapur waters (19 degrees 54'N and 72 degrees 41'E) which receives rad waste from a 400 MWe BWR. To understand these problems, emphasis is placed on radioecology and biogeochemistry of indicator species in relation to environment and radiobiology to evaluate the effects of ionizing radiations on the blood of selected marine species.

The regular monitoring is followed to assess the capacity of local marine environments to receive rad wastes and to derive maximum permissible radioactive contamination limits in the hydrospace. The hydrographic studies - current patterns, salinity, temperature - are carried out to study the dispersion of radioactivity and movement of water masses, silt transport and deposition.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

2.0137, THERMAL AND BIOLOGICAL CHARACTERISTICS OF LAKES
R.G. LIPSCOMB, U.S. Dept. of the Interior, Geological Survey, *Fort Wayne, Indiana* 46803

The project is to evaluate methods of evaporation computation, study thermal-stratification processes, investigate biological influences on water quality, and study the process of lake aging. Where practical, new investigative techniques will be developed. Time and spatial distribution data from detailed counts of algal species in Pretty Lake, LaGrange County, Indiana, are being related to the distribution of water temperature and of chemicals known to be important in growth processes. Wind, temperature, and radiation data are being used in the study of water temperatures and evaporation. Analyses of plant and animal remains in the lake sediments, along with other sediment analyses, will provide data for the study of the aging process in Pretty Lake.

2.0138, SALINE WATER RESOURCES OF INDIANA
T.M. ROBISON, U.S. Dept. of the Interior, Geological Survey, *Indianapolis, Indiana* 46204

2. WATER QUALITY

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of Indiana.

Purpose: To defined the area of pollution of ground water aquifers by saline waters from oil field operations, pinpoint the source, and monitor the pollution.

Methods: Sites are selected in coordination with the State Oil and Gas Division and the State Geological Survey. The following sites are under study: 1) An area of new oil wells with no reported pollution of ground water 2) An area of both old and new oil wells with only a rumor of pollution of ground water 3) An area where known pollution ground water has occurred.

Field and laboratory analyses are made to determine the extent of pollution. Periodic sampling and analyses of water from selected wells monitor the movement of pollution.

2.0139, PATTERNS OF PESTICIDE CONTAMINATION OF WATER

L. CHANDLER, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01480)

OBJECTIVE: Determine interrelationships of pesticides and soils with respect to water transport and/or deposition. Analyze the biotic significances of earthworms and stoneflies in multidimensional quantitative systems.

APPROACH: Class-representative insecticides will be applied at several concentrations to columns of soils. Water will be percolated through each and analyzed by gas liquid chromatography. Columns will be analyzed to determine depositions. Large-scale simulation will be conducted to establish significance of lateral movements. Baseline data will be obtained by studies of stoneflies and earthworms at stream and floodplain sites and in the laboratory. Methods of quantitative ecological analyses will be developed.

PROGRESS: Species of winter stoneflies (Allocapnia spp.) were studied to determine: the factors related to coexistence, the basic life histories of our common species, the value of species as ecological indicators of stream conditions, and the major mortality factors. Preliminary results were obtained for all objectives as follows: competition among species is reduced by differences in seasonal development of the immatures and/or substrate preferences; development from eclosion to emergence is extremely rapid, the greatest period of time being spent in the egg stage (8-11 months); species are good indicators of certain specific factors but should not be used in the generalized sense of indicators; and silting and catastrophic flooding are the two most important mortality factors. Population predistions can be made on the basis of current speed as related to gravel-sand substrate.

SUPPORTED BY U.S. Dept. of Agriculture

2.0140, THE FACTOR CONTROLLING THE DYNAMICS OF NON-IONIC SYNTHETIC ORGANIC CHEMICALS IN AQUATIC ENVIRONMENTS

J.L. HAMELINK, Purdue University, School of Agriculture, *Lafayette, Indiana* 47907

Project objectives include: 1) Evaluation of the adsorption of non-ionic organic chemicals (NISOC) to intact and suspended lake sediments in water; 2) Evaluation of the desorption of NISOC's from intact and suspended lake sediments into water; 3) Evaluation of the influence of increasing organic matter content in the sediments has on persistence and recycling of NISOc's; 4) Evaluation of the influence of increasing organic matter content in the water has on persistence, biological magnification and recycling of NISOC's in lentic environments; 5) Initiate development of an evaluation procedure to be used for defining water quality standards governing NISOC's; 6) Development of economically feasible practices or treatments to reduce NISOC residue levels in contaminated lentic environments, and 7) Evaluation and comparison of the persistence of brominated and chlorinated NISOC's in lentic environments.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0141, FATE OF SURFACE-APPLIED NITROGEN FERTILIZERS

P.G. MOE, Purdue University, Agricultural Experiment Sta., *Lafayette, Indiana* 47907 (IND01471)

OBJECTIVE: Determine amount of fertilizer nitrogen lost in surface runoff water and through leaching; determine the extent of ammonia volatilization and denitrification losses; determine the amount of fertilizer nitrogen immobilized by soil microorganisms and/or fixed in unavailable forms in the soil; determine ways of improving crop utilization of nitrogen fertilizers.

APPROACH: The fate of nitrogen fertilizers applied to well characterized field plots will be followed over an annual cycle. A rainfall simulator will be used to provide controlled amounts of precipitation for measuring nitrogen losses due to surface runoff and leaching. Laboratory incubation experiments will be used to measure volatilization losses and N-15 labeled fertilizers will be used to measure immobilization.

PROGRESS. Simulated rainfall field plot experiments were used to study the loss of nitrogen fertilizers in surface runoff water. Total nitrogen losses from ammonium nitrate treated plots were about double the losses observed on the urea treated plots. This was due to a deeper penetration of the urea into the soil. Delaying the rainfall application to 5 days after fertilizer application increased nitrogen losses from all plots due to an increase in nitrate nitrogen loss. Maximum nitrogen loss under the most severe conditions amounted to only about 15% of the applied fertilizer nitrogen.

2.0142, NUTRIENT CYCLING AND PRODUCTIVITY OF DYSTROPHIC LAKE-BOG SYSTEMS

T.C. GRIFFING, Univ. of Notre Dame, School of Science, *Notre Dame, Indiana* 46556 (AT(11-1)-1770)

A bog lake system will be chemically manipulated with lime to substantially increase the alkalinity in order to test the effects of alkalization on the major systems components which regulate productivity and nutrient cycling. One primary factor which will receive particular attention is the soluble brown staining organic that restricts light penetration, binds nutrients and contributes to the acidity of the system.

Results to date: A model has been developed that describes the pathways of nutrient cycling and hydrographic flow in perched bog systems. Comprehensive decriptions of the absorption coefficients of high molecular weight dissolved organics have been determined which demonstrate the regulatory effects on light in the trophogenic zone. Primary productivity has been markedly stimulated by the addition of alkaline earth cations.

SUPPORTED BY U.S. Atomic Energy Commission

2.0143, EUTROPHICATION OF IOWA LAKES AND STREAMS

R.W. BACHMANN, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01779)

OBJECTIVE: Determine the critical nutrients responsible for eutrophication in Iowa waters.

APPROACH: Carbon-14 algal bioassays will be run on selected natural waters to determine which nutrients are critical to algal production. Quantitative chemical studies will be made of these critical elements to determine their sources and cycles within the water body in question. A search will be made for means to disrupt the cycles of critical elements.

PROGRESS. Major efforts have been expended in setting up the laboratory facilities to carry out the carbon-14 nutrient bioassays. A constant temperature, illuminated incubator has been constructed with provision for magnetic stirring of the experimental cultures. Bioassays of water samples from the Des Moines River will begin during the coming year. A sampling program was initiated on 17 streams and 7 lakes in the central Iowa region. Analyses are being made of plant nutrients and algal populations for the purpose of providing baseline information of the state of eutrophication of these waters.

SUPPORTED BY Iowa State Government - Des Moines

2.0144, EUTROPHICATION OF IOWA LAKES AND STREAMS
R.W. BACHMANN, Iowa State University, School of Agriculture, *Ames, Iowa* 50010

Many Iowa lakes and reservoirs are highly eutrophic as evidenced by chemical composition, algal blooms and winter oxygen depletions. It is important to determine the fundamental reasons for this excess productivity in order to evaluate the potential benefits of programs designed to reduce nutrient inputs through more elaborate municipal and industrial waste treatment plants, restrictions of feedlot waste disposal or restrictions on other agricultural practices that contribute nutrients to Iowa lakes and streams.

Objectives: 1. To examine the plant nutrient status of selected Iowa lakes and streams in order to determine where possible the sources of nutrients, their cycles within the water body and their ultimate points of loss to the biological system. 2. To determine by bioassy procedures which nutrients are in critical supply. 3. To examine the feasibility of controlling the supply of critical nutrients.

SUPPORTED BY Iowa State Government - Des Moines

2.0145, STUDY OF SEDIMENT POLLUTION AND MOVEMENT BY ACTIVATION ANALYSIS PRINCIPLES
C.E. BEER, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01766)

OBJECTIVE: Determine the sources of sediment contributing to the pollution of streams and rivers. Determine the pattern of sediment movement in a field to check theoretical mechanics of erosion equations. Determine the change in total sediment load per unit of area as watershed size increases. Relate sediment production to storm characteristics.

APPROACH: In activation analysis certain elements are irradiated with nuclear particles to produce radioisotopes. By counting the rate of disintegration of these radioisotopes, a quantitative evaluation of the amount of the original element present is possible. The field procedure will involve mixing Lanthanum in soil on a large scale to produce a 'seeding' batch. The treated soil may then be placed in the field at predetermined points chosen to fulfill a given objective. Sampling would be done immediately after seeding and at any other points along the flow path where information is desired.

PROGRESS: The major accomplishments during the 6-month period since the project was funded are as follows: A data acquisition system has been developed whereby data from a pulse height analyzer can be transmitted directly through teletype to a main computer. Output is then secured as a remote job entry. Limited seeding of soil-lanthanum mixtures was done on a small watershed on the Western Iowa Experiment Farm. Samples have not been completely analyzed. Agreements with the U.S. Geological for cooperative operation of 3 sediment-flow gaging stations in Four Mile Creek have been completed. These watersheds will be instrumented in 1970. In a related project entitled 'Relationship of Hydrology and Soils to Gully Development', a review of literature has been made.

SUPPORTED BY Iowa State Government - Des Moines

2.0146, STUDY OF SEDIMENT POLLUTION AND MOVEMENT BY ACTIVATION ANALYSIS PRINCIPLE
C.E. BEER, Iowa State University, School of Agriculture, *Ames, Iowa* 50010

In activation analysis certain elements are irradiated with nuclear particles to produce radioisotopes. By counting the rate of disintegration of these radioisotopes, a quantitative evaluation of the amount of the original element is possible. The field procedure will involve mixing lanthanum in soil on a large scale to produce a 'seeding' batch. The treated soil may then be placed in the field at predetermined points chosen to fulfill a given objective. Sampling would be done immediately after seeding and along flow path where information is desired.

A 14 mi square watershed will be used in the study. The sediment and nutrient loads (N, P) will be obtained from 3 gaging stations, each controlling sucessively larger areas.

2.0147, WATER EROSION MECHANICS AND CONTROL--DEEP LOESS HILLS AND TILL PRAIRIES
W.C. MOLDENHAUER, Iowa State University, U.S.D.A. Soil & Wa. Cons. Div., *Ames, Iowa* 50010 (SWC-016-CAMES-1)

OBJECTIVE: Develop fundamental concepts explaining influences of soil physical and chemical properties on soil detachment and transport by rainfall and runoff, develop methods to bring subsoils exposed by topographic modification to optimum production level; characterize runoff and erosion problems in this resource area.

APPROACH: Continue investigations to define role of soil and its management in erosion processes. Develop techniques for analysis of and identify factors that influence soil aggregation and surface seal and find their relation to infiltration and erosion. Study physical and fertility relationships on exposed subsoils to find limits of economic feasibility of topography modification.

PROGRESS: Increased production of row crops, especially soybeans, coupled with reduced dairying have resulted in critical soil conservation problems in the Corn Belt. In Iowa, for instance, more than 17 million acres are in corn and soybeans. To obtain this acreage, more and more rolling to steep land has been cropped. Uncontrolled erosion causes land deterioration, soil and water losses, and contributes to pollution by sediment, pesticides and nutrients. The only apparent solutions at this time are soil- and water-conserving tillage methods on lower slopes in conjunction with large-scale topography modification, such as grassed back-slope terraces, on slopes too steep for erosion control by tillage methods alone. Fields cropped to a 2-year system of corn and soybeans are likely to lose significantly more soil by erosion than fields cropped to corn each year. But the increased erosion occurs in the year after the soybeans rather than while they occupy the land. Average annual soil loss from the soybeans following corn just equaled that from corn following corn, but soil loss from the corn following soybeans was 40 percent greater. Average annual soil loss from corn following soybeans was 8.5 tons per acre in contrast to 6.1 tons from each of the other two cropping sequences (losses adjusted to 300 foot slope length). Soil loss from corn following soybeans was not only greater than that from continuous corn in each year of the test but also within the season whenever erosive rains occurred.

2.0148, EFFECT OF MINERAL ELEMENTS ON YIELD AND COMPOSITION OF CROPS AND ON SOIL CONDITIONS
J.R. WEBB, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01761)

OBJECTIVE: Acquire basic information concerning crop response to fertilizer rates and practices, devise means of predicting these responses under different cultural and environmental conditions, and study soil chemical conditions as influenced by fertilization practices.

APPROACH: Continue operation of established long-term experiments involving fertilizer and lime variables, with crop yield response, crop chemical composition and soil nutrient level evaluation being emphasized. Study the movement and fate of high rates of fertilizer in the soil and relate the results to crop response and potential pollution of ground water. Investigate levels of secondary and micronutrients in various soils and crops, characterize any observed deficiencies, and study corrective practices. Incorporate the research results into efficient fertilizer recommendations for crops grown under various conditions.

PROGRESS: Results for the period covered are largely from previously established long-term experiments involving soil fertility variables. These results indicate that (1) Well fertilized crops of corn and soybeans continue to show little or no response to lime. Liming to produce a soil pH in the 7.5 to 7.7 range has had no apparent adverse effect on the growth or yield of these crops. (2) Continuously grown corn which has received up to 1200 pounds N, 450 pounds P, and 900 pounds K per acre for five consecutive years continues to yield well (over 150 bushels) and show few harmful effects. Rates of 600 pounds or more of N have depressed germination and early season growth when applied

shortly before planting or when not well mixed through the plow layer. All N rates (200 to 1200 pounds) have reduced the pH of the 0-6 and 6-12 inch layers of soil and after the fifth application of 1000 and 1200 poundsrates measurable decreases in the pH of the 12-18 inch layers were evident. (3) N fertilizer effectiveness on corn has been influenced some by time of application at some sites. Fall, spring, and early summer was the order of increasing efficiency where differences were observed, (4) Zinc fertilization gave small corn yield increase on two sites which had not previously responded.

SUPPORTED BY Iowa State Government - Des Moines

2.0149, PROPERTIES OF TILE DRAINAGE WATER
T.L. WILLRICH, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01655)

Progress: Grab samples were collected only twice from the outlets of ten tile drainage systems during the spring and summer months because precipitation amounts and frequency of occurrences were not sufficient to cause tile flow except for short time intervals. The samples were analyzed for total nitrogen, phosphorus, potassium, total hardness, total alkalinity, sulfate and chlorinated hydrocarbon residual concentrations in addition to temperature, pH and specific conductance. Because of the limited number of samplings, quantitative values obtained during this year will be reported in the terminal report along with values obtained during the previous three years of investigation

2.0151, FERTILIZATION EXPERIMENTS IN THE EASTERN MEDITERRANEAN COASTAL WATERS
O.H. OREN, Israel Sea Fisheries Res. Sta., *Haifa, Israel*

The objectives of this project are: 1. Determination of leaching rate of phosphates from the ore wastes of Oron, under various conditions, in sea water. 2. Evaluation of nutrient value of these ores on planktonic organisms, under laboratory conditions, using the C14 method. 3. Evaluation of nutrient value of liquid and solid urban wastes. 4. Evaluation of plankton population, taxonomic studies of the phyto- and zooplankton, chemical analyses of water within semi enclosed bays along the shore. 5. Observations on fish population in the vicinity of sewage pipes in the sea. 6. Analysis of the changes in productivity of Isralie coastal waters following impoundment of the Nile River.

2.0154, DISTRIBUTION AND CYCLE OF RADIONUCLEOTIDES AND RELATED TRACE ELEMENTS IN MARINE ENVIRONMENT
B. SCHREIBER, Univ. Degli Studi, *Parma, Italy*

Our programme comprehends the radioactivity study of plankton, necton, benthos, sea water and sediments in the Taranto Gulf in view of the fact that in the near future radioactive effluents will be released into the Jonian Sea from a reprocessing plant.

As in the past, we are particularly interested in the study of plankton, mainly for the eventual presence of Acantharia that we consider good accumulators of radioactive strontium.

In our laboratory the study of Acantharia is highly important also for the collaboration, established many years ago, with Dr. W.T.Bowen, of the Woods Hole Oceanographic Institution, who entrusted Prof. E. Massera Bottazzi with the systematic-ecological study of Acantharia in the Atlantic Ocean.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

2.0155, EFFECT OF URBANIZATION ON WATER QUALITY
E.E. ANGINO, Univ. of Kansas, Graduate School, *Lawrence, Kansas* 66044

The problem of water quality and contamination by the environment is one of the most challenging areas for research in our society. However, the more specific problem of the effect of urbanization on water quality has been essentially ignored. A search of literature reveals few good papers dealing with this problem.

We propose to examine this problem by investigating the quality of runoff water draining the south part of the University of Kansas campus and exiting down the Naismith channel. The study will include an investigation of seasonal, sudden storm, and dry period effects as reflected in the 10 water quality parameters: Biological oxygen demand, chemical oxygen demand, coliform count (total and fecal), solids content (total, dissolved, and volatile), nitrate phosphate, pH, temperature, and chloride.

Our objectives are: (1) to determine time-distribution of water quality both on a seasonal basis and in response to runoff following a heavy rainstorm. Little information of this type is available in the literature. 2) to determine the feasibility of using urban runoff as a supplemental municipal water source from a water quality standpoint. 3) to compare runoff quality between an open residential area (Lawrence) and a mixed-industrial-city urban area (1 paper in literature). 4) to ascertain whether climatic differences are evident in quality of runoff water.

SUPPORTED BY Kansas State Government - Topeka

2.0156, EFFECT OF NITRATE AND NITRITE IN THE DRINKING WATER ON PERFORMANCE OF MARKET TURKEYS
A.W. ADAMS, Kansas State University, Agricultural Experiment Sta., *Manhattan, Kansas* 66502 (KAN-05-692)

OBJECTIVE: Define the lethal toxic levels of nitrate and the accompanying external and internal changes of poults grown to various ages.

APPROACH: The study with market turkeys will be repeated.

PROGRESS: Using sodium salts, levels up to 7980 ppm nitrate were added to well water of Broad Breasted Bronze poults from day-old to various ages. The three highest levels (5320, 6650 and 7980 ppm) proved lethal by the fifth day post treatment. Results suggest that adverse effects of high levels of sodium nitrate were due to excess nitrate rather than sodium ions. Up to 1485 ppm nitrate had very little effect on body weight, feed and water consumption, mortality and blood hematocrit values of 24-week old turkeys. Necropsies indicated sodium nitrate and/or acetate caused an enlargement of kidneys. No consistent relation-

ship was observed between these materials and incidences of atypical conditions in tissues from the brain, intestines, liver and spleen. Data suggest 660 ppm nitrate gave a delayed growth response, particularly in males, when administered to 4-weeks of age. No significant change in meat color was observed when nitrates were added to the drinking water at levels up to 1485 ppm. Nitrates in chill water at 600 ppm significantly increased intensity of pink color. Uncooked meat showed more pink color than cooked meat. Ground cooked meat revealed less intensity of red color than unground cooked meat.

SUPPORTED BY Kansas State Government - Topeka

2.0157, MODELING AND OPTIMIZATION OF THERMAL POLLUTION CONTROL SYSTEMS
C.L. HWANG, Kansas State University, School of Engineering, *Manhattan, Kansas* 66502

There is an urgent need for gaining a better understanding of the physics of heat input, and transport and dissipation of water resources. There is also a need for designing improved discharge outfalls and finding optimal discharging policy for cooling water. This proposed research is to develop mathematical models for prediction of temperature and dissolved oxygen (DO) concentration distribution of a stream receiving cooling water discharges from power plants or other industrial processes, to carry out computer simulation of thermal pollution and various thermal pollution control policies based on the mathematical models, to determine the optimal design and operating policies of thermal pollution control systems for power plants or industrial plants which produce a large amount of waste heat effluent, and to develop additional optimization techniques and computational algorithms which can be applied to the optimization of the thermal pollution control systems.

2.0158, LIMNOLOGICAL SURVEY OF SURFACE WATERS OF THE COTTONWOOD-NEOSHO DRAINAGE IN CHASE, LYON, AND COFFEY COUNTIES, KANSAS
C.W. PROPHET, State Forest. Fish & Game Com., *Pratt, Kansas* 67124

P.S Objective: To assess the relative contribution of nitrate, phosphate, and coliform bacterial levels to the Cottonwood-Neosho River Basin from natural and agricultural sources and to determine coliform bacterial utilization by fish and selected fish-food organisms.

Procedures: 1. Quantify the seasonal nutrient and coliform bacterial levels in selected lakes and ponds along the Cottonwood-Neosho Basin and determine whether there are significant changes in nutrients and coliform densities within 24-28 hours of precipitation in excess of 0.5 inch. 2. Quantify the nutrient and coliform bacterial levels in streams and water courses of a restricted watershed in which there are no known sources of contamination during non-runoff and within 24-48 hours of precipitation in excess of 0.5 inch. 3. Record complimentary physicochemical data from each selected lake or stream which can assist in characterizing their relative environmental quality (temperature, pH, BOD, suspended solids dissolved solids, and dissolved oxygen). 4. Estimate standing crops of major planktonic and benthic fish food organisms in the study systems. 5. Determine coliform bacterial utilization by fish and selected fishfood organisms.

2.0159, REDUCTION IN DAMAGES TO FORESTS BY IMPROVING MINING AND REHABILITATION PROCEDURES
G. DAVID, Berea College, U.S.D.A. Northeast. For. Sta., *Berea, Kentucky* 40403 (NE1605)

OBJECTIVE: Develop practical methods to reduce watershed damage and water pollution during mining and to restore the wildlife, recreation, water, range, and timber resources after mining in the rugged forested watersheds of the Appalachian coal fields.

APPROACH: Basic study of mechanics of rock-soil mixtures, spoil- bank chemistry, and hydrologic processes and plant-soil-water relationships on strip mines; cooperative research and development with other organizations and operators to improve methods of excavating, placing and storing overburden, construction and maintenance of coal- haul roads, and mined-area stabilization by structures and vegetation.

PROGRESS: From our hydrologic studies of strip-mined watersheds in Eastern Kentucky it appears that sedimentation is the most serious overall water pollution problem. Acid pollution is also serious on many small severely disturbed watersheds, but generally it is not important in the larger watersheds or major rivers. A knowledge of spoil acidity and fertility is necessary for planning revegetation programs. For determining pH of mine spoils the LaMotte-Morgan method agreed more closely with a pH meter than did other 'field-kit' methods. The Bray 01 soil test for phosphorus gave meaningful results on spoils derived from soft Pennsylvanian shales, whereas stronger acid solutions for extracting P gave results that were misleading. Ameliorative treatments are sometimes needed to establish vegetation on spoils with certain adverse physical and chemical characteristics. Surface density of spoil was initially lessened by scarification but this influence was of short duration. One year after extremely acid spoil was mulched with hardwood chips the pH of the surface foot of spoil was raised while total salts and water soluble aluminum were reduced. Liming increased growth of four species of pine on extremely acid bituminous spoil; it was essential for the survival of trees planted on anthracite breaker refuse.

2.0160, WATER POLLUTION AND ITS CONTROL BY MICROBIAL METABOLIC ACTIVITIES
M.I. ALEEM, Univ. of Kentucky, School of Biological Sciences, *Lexington, Kentucky* 40506

It is well recognized that biological as well as non-biological transformations of organic and inorganic materials are the main cause of water pollution. The activities of sulfur oxidizing and sulfate reducing bacteria are known to be responsible for many of the characteristics of the acid mine wastes. In the proposed program emphasis has been given to the biochemistry of the oxido-reduction reactions of sulfur and nitrogen compounds, and the factors involved in the control of such microbial metabolic activities in order to seek a solution to the problems involved in the water pollution. Experiments are also described concerning the employment of biological systems capable of removing toxic sulfur compounds such as sulfides and sulfates from polluted waters most economically.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0161, THE RELATIONSHIP BETWEEN ALGAL GROWTH AND THE AVAILABILITY OF CARBON
R.A. LAUDERDALE, Univ. of Kentucky, School of Engineering, *Lexington, Kentucky* 40506

The objective of this project is to demonstrate that it should be possible to prevent the growth of algae in excessive amounts by controlling the amount of available carbon in the water.

This objective will be accomplished by determining the interrelationships between the amounts of inorganic and organic carbon present in a water and the amount of algal growth which can be sustained. More specifically the project will determine: (1) The level of growth which can be maintained if the sole source of carbon is the carbon dioxide available from the atmosphere. (2) The level of growth which can be maintained if the source of the carbon available is governed by the carbonate -bicarbonate equilibrium in water. (3) The level of growth resulting from a combination of (1) and (2). (4) The level of growth which can be maintained in a bacteria free medium containing various concentrations of organic carbon. (5) The level of growth which can be maintained in an organic medium in which bacteria also are present. (6) The level of growth resulting from combinations of the above.

2. WATER QUALITY

2.0162, DEGRADATION OF RIPARIAN LEAVES AND THE RECYCLING OF RELEASED NUTRIENTS IN A STREAM ECOSYSTEM

L.A. KRUMHOLZ, Univ. of Louisville, Graduate School, *Louisville, Kentucky* 40208

The recycling of naturally occurring organic and inorganic nutrients is important in the study of aquatic systems. Leaf fall from riparian streams has a profound effect on the chemical composition of the water in the adjoining watercourse and an oversupply of such allochthonous material can cause drastic changes in the biota. The decomposition of such leaves after they enter the water releases nutrients from the leaves themselves but also utilizes large amounts of oxygen. The roles of such nutrients as proteins, carbohydrates, and lipids in the overall budget of the stream are not well known. However, some workers have pointed out that as much as half or two-thirds of the total energy budget may come from such sources.

Changes in the amounts of proteins, carbohydrates, and lipids will be measured as they are released into the stream over a period of about 4 months. In addition, calorific equivalent values for leaves from different species of trees will be measured and those values correlated with values for released nutrients.

This project is part of an overall study of a stream ecosystem and the results will be correlated with changes in the biota and the physical characteristics of the stream.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0163, THRESHOLD ODOR DETERMINATIONS OF WATER SAMPLES FROM THE LOWER MISSISSIPPI RIVER

M.R. RAD, Louisiana State University, Agricultural Experiment Sta., *Baton Rouge, Louisiana* 70803 (LAB01504)

OBJECTIVE: Determination of the threshold odor values of the Lower Mississippi River water samples by a panel of judges. The values will be compared to the data obtained by chemical, microbiological and instrumental analysis. This study helps to make recommendations to eliminate the off and obnoxious odors associated with the Mississippi River and drinking water.

APPROACH: The threshold odor values of the water samples will be determined by a panel of judges consisting of at least 10 members who have had experience in organoleptic evaluation. The test will be run by the consistent series method as outlined in 'Standard Methods for the Examination of Water and Waste water', Twelth Ed., 1965, with modifications wherever it is found appropriate.

PROGRESS: An investigation was performed to determine if the odor of water can be used as an index of pollution, and to study the effects of the environment on the odor content of water in the lower Mississippi River area. Results obtained indicate that the odor level in the raw river water may be used as an index to pollution if the effects of river temperature and stage are taken into consideration. There was a low degree of correlation between the threshold odor values of the raw river and finished drinking waters. After analysis, the effects of temperature and river level were found to be very significant. The results of the analysis showed that the variation due to source and station were not significant. The actual effects on each station due to temperature and river stage varied. Equations showing the degree of variation in the effects of river temperature and stage on the odor content of the raw river water were derived for each sampling station. Other factors are probably involved which influence odor content in the raw river water, and should be considered before odor intensity is used as an index of pollution.

SUPPORTED BY Louisiana State Government

2.0164, THE COLIFORM BACTERIA, PLANKTON, & RELATED PHYSICO-CHEMICAL FACTORS IN LAKE PONTCHARTRAIN AT NEW ORLEANS, LA

D.H. STERN, Louisiana State University, Graduate School, *New Orleans, Louisiana* 70122

A summer study of the coliform bacteria, the plankton, and related physicochemical factors in Lake Pontchartrain at New Orleans will be carried out in 1969. The area of concentration in the lake will be that adjacent to the sewerage outfall canals and public recreation areas (Fig. 1). Cruises will be run each week, beginning in late May or early June. The cruise stations will be selected so as to sample inshore lake waters adjacent to unchlorinated outfall canals, canals being experimentally chlorinated by the New Orleans Sewerage and Water Board, public beaches, and areas used for general aquatic recreation.

During each cruise the following shipboard analyses will be made: residual chlorine, pH, methyl-orange and phenolphthalein alkalinities (surface waters); water temperature, dissolved oxygen concentration, specific conductivity, salinity (profiles - 1 M intervals); and Secchi disc transparency. In addition water will be collected for coliform bacteria counts, plankton tows will be made, and additional water samples will be collected for laboratory analyses. In the laboratory differential plankton counts will be made, and water samples will be analyzed for turbidity, solids, chloride ion, nitrogen states, phosphates, and Biochemical Oxygen Demand. Total and fecal coliform counts will be carried out using the membrane-filter technique.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0165, WATER QUALITY DEGRADATION BY SEPTIC TANK DRAINAGE

M.W. HALL, Univ. of Maine, School of Engineering, *Orono, Maine* 04473

This research is aimed at determining the quantities of nitrogenous and phosphatic materials that enter Maine lakes from septic tank drainage. Laboratory studies were focused on determining phosphorus (a) upstate, (b) retention, (c) movement, and (d) changes induced by freezing-thawing in three soils series: the Paxton, Adams, and Plaisted. All soils exhibited a large retention capacity, the rating being Paxton, Plaisted, and Adams in decreasing order of capacity. Although important, differences in phosphorus fixation were found to be not attributable solely to iron and alumina content. Fixation was also related to parameter of standard particle size analyses. Acidity may be an important parameter.

Results to date show that soil capacity to fix phosphorus is readily exhausted by natural conditions regardless of the presence of favorable soil characteristics. Freezing and thawing is seen to lessen the retention capacity of soils for phosphorus. Septic tanks are considered to be effective phosphorus 'traps' only when large leaching areas are available and when the groundwater table exerts no influence.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res Rch.

2.0166, AN INVESTIGATION OF THE CAUSES, EFFECTS, AND CONTROL OF EUTROPHICATION IN MAINE LAKES

M.W. HALL, Univ. of Maine, School of Technology, *Orono, Maine* 04473

This study provides field and laboratory data relative to several parameters thought to be important in the control of lake aging, soils, nitrogen and phosphorus concentration, alkalinity, temperature, pH, water clarity, lake morphology, etc.

The field data obtained is being used to determine: (1) The nutrient levels responsible for nuisance algal conditions in selected Maine lakes. (2) The effect of other selected parameters on critical nutrient levels. (3) The rate of change in nutrient levels in several Maine lakes, and the causes of this change. (4) The effects of the removal of major sources of nutrients on algal conditions in the lakes' waters. (5) The effect on the progress of algal development caused by biological treatment of wastewaters which eventually enter lakes.

2.0167, PHOSPHATE RETENTION BY LAKE SEDIMENTS AS A FACTOR IN THE EUTROPHICATION OF LAKES

E.G. LOTSE, Univ. of Maine, School of Agriculture, *Orono, Maine* 04473

The purpose of the proposed research is to elucidate the influence of various factors governing the equilibria between phosphorus in lake waters and phosphorus in the lake sediments and to evaluate the long- range effect of phosphate retention by lake sediments on the eutrophication of lakes. To accomplish this, the effect of mineralogical and chemical composition of the sediments, equilibrium phosphorus concentration, pH, reaction time, solid to solution ratio, and phosphate to sediment ratio on phosphate retention will be studied, and different forms of phosphorus in the sediments will be determined. The rate and extent of phosphate retention by sediments and model substances such as pure clay minerals, hydroxides of iron and aluminum, and clay minerals with hydroxy-iron and hydroxy-aluminum interlayers will be determined by equilibration with 32 PO4-31 PO4 solutions of known concentration. It is expected that the proposed research will lead to new knowledge of the basic principles of phosphate retention and contribute substantially to the understanding of phosphorus accumulation in lakes. The findings would also be of great significance in evaluating methods for removal of soluble phosphate from waste effluents and in evaluating the effects of future land use practices.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0168, AREAL DISTRIBUTION AND PROVENANCE OF SEDIMENTS IN ST. GEORGE RIVER, KNOX COUNTY, MAINE

L.K. FINK, Univ. of Maine, Ira C. Darling Ctr. for Res., *Walpole, Maine* 04573

Sediment cores are being collected from the St. George Estuary. Grain size analyses and heavy mineral suites will be determined. This information will be used to determine areal distribution of the various heavy mineral suites and the provenance of the sediments in the St. George River. The possible contamination by pollutants of the estuary's sediments will be considered. The parameters which will define a signature of a specific estuary will be determined and will form the basis for further studies in other estuaries of the Maine coast.

SUPPORTED BY Maine State Government

2.0169, EVALUATION OF THE MAGOTHY AQUIFER - ANNAPOLIS AREA, MARYLAND

F.K. MACK, U.S. Dept. of the Interior, Geological Survey, *Baltimore, Maryland* 21204

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of Maryland.

Purpose: To evaluate the quantities of water available in the Magothy aquifer and the possible hazard of salt-water contamination. To provide the knowledge necessary for proper development and management of the ground-water resources.

Methods: About 15 sites will be selected for test drilling, pumping tests, measurement of water levels, and collection and analysis of water samples. Geologic data and hydraulic coefficients, both for the Magothy aquifer and the overlying sands of the Monmouth and Aquia Formations will be obtained at the test sites. The permeability of the aquicludes separating the aquifers will be determined. An electric analog model will be constructed and used to predict effects of hypothetical pumping and for planning development and management of the Magothy aquifer.

Project started in 1968 and will be completed in 1971.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0170, CONTROL OR PREVENTION OF SOIL AND WATER POLLUTION FROM FERTILIZERS

A.W. TAYLOR, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Beltsville, Maryland* 20705 (SWC-027-AB-5)

OBJECTIVE: Determine the nature of the transformations of nitrogen fertilizers in soils that lead to the formation of nitrate or nitrite ions, and examine the factors that control the amounts of these ions and other nutrient elements moving into lakes, streams, and subsoil waters.

APPROACH: Experiments are conducted to study the transformations of soil and fertilizer nitrogen that lead to the formation of nitrate ions in soils, using chemical extractions, N -labelled tracer techniques, and incubation procedures to evaluate microbiological effects. Data obtained are evaluated in terms of rates of field applications of nitrogen and hydrologic data on water movement. Phosphate movement is measured by analyses of water samples from watershed where hydrologic measurements are made, and evaluated in terms of phosphate adsorption by associated soils and sediments. Adsorption isotherms are measured in laboratory studies using both unlabelled and phosphorus-32 labelled solutions.

PROGRESS: Losses of P through leaching or erosion from an agricultural watershed heavily fertilized with P is very small. Equilibrium studies demonstrate that sediment will continue to adsorb the P from stream water as a function of time. Losses of N and K from farmland were about twice those from woodland. Losses of these nutrients were sporadic, occurring almost entirely during the small portion of the year when water flows are highest. Stability of soil microaggregates in affecting accessibility of microorganisms to organic N may be one of the major factors in determining relative mineralization rates of recently incorporated N fertilizer, and of indigenous forms of soil N. Physical disruption of microaggregates by ultrasonic dispersion resulted in increased N mineralization. Need for controlling N fertilizer use within reasonable bounds has prompted continued effort in developing a reliable method in assessing the available N status of soils. A number of soils representing a wide array of chemical and physical properties were used to evaluate chemical methods for determining the available N status of soils. Results show that chemically extracted N clearly reflects relative biological availability as determined by plant uptake and N mineralization during aerobic and anaerobic incubation.

2.0171, KINETIC STUDIES OF THE OXIDATIVE DEGRADATION OF DETERGENT, AND RELATED CHEMICAL SPECIES IN AQUEOUS SOLUTION

R.B. BECKMANN, Univ. of Maryland, School of Engineering, *College Park, Maryland*

This is a joint research effort of the Department of Microbiology and Chemical Engineering to study the fundamental biological, and physical-chemical and engineering aspects of the biodegradation process for LAS detergents and to explore the similar fundamental aspects of alternative oxidation routes. Phase I is to be investigated by utilizing a pure (insofar as is possible) LAS derivative, such as A- Dodecene Benzene Sulfonate (or other alkyl derivative in the C12-C15 linear alkyl range) and investigate the rate of degradation in 'synthesized' systems; the systems being 'synthesized' in that the LAS, bacterial, and dissolved oxygen contents will be controlled and the intermediate products and end products will be continually monitored. Once the specific intermediate products have been identified, rate studies will also be carried out using these intermediates as starting materials. By utilizing the 'synthesized' reaction systems in this initial stage, a 'control' or 'ground state' can be established for extension of the kinetics into the realm of industrial or multicomponent mixtures, and it will also serve as a comparative base for the second (II) and concurrent phase of the project. The LAS concentration range covered will be that anticipated in normal effluents 10-1000 parts per million with ultimate extension to the more concentrated regions that might be encountered in sludges.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0172, HIGHWAY DRAINAGE STUDY

R.M. RAGAN, Univ. of Maryland, School of Engineering, *College Park, Maryland* (2R23080378)

The project reviews current surface & sub-surface drainage practices in various parts of Maryland. Hele-Shaw and electrical analog experiments have been used to test numerical models developed to synthesize the conditions around a longitudinal drain as a result of localized infiltration. Work on a design-storm model for the computation of surface runoff is being pursued.

Document provided to SIE by the Highway Research Information Service.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Transportation - F.H.A.

2.0173, THE TRANSIENT BEHAVIOR OF RECHARGE-DISCHARGE AREAS IN REGIONAL GROUND WATER SYSTEMS
R.M. RAGAN, Univ. of Maryland, School of Engineering, *College Park, Maryland*

The circulation of ground water under large areas of the Atlantic Coastal Plain is such that local and intermediate subsystems develop within the overall ground water reservoir. Often these sub-systems have little or no flow moving from one system to the other. The result is that recharge, discharge, and the extent of aquifer pollution caused by the introduction of contaminants could be controlled by local areas of the land surface. The study is directed toward a better means of predicting the lateral and vertical movement of contaminants that might enter such a ground water system as a result of the land disposal of municipal or industrial wastes. The initial efforts will be devoted to numerical studies using the differential form of the continuity and momentum equations in which the inertial terms are not neglected.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0174, POLLUTION LOADS IN RUNOFF FROM SMALL AGRICULTURAL WATERSHEDS
W.F. SCHWIESOW, Univ. of Maryland, School of Agriculture, *College Park, Maryland* 20742

A gaging station and automatic sampler are to be installed at the discharge point of a small agricultural watershed. The watershed to be selected should be between two and twenty acres in size. A larger area may be used if other factors make it impossible to locate a suitable watershed having less than twenty acres. Flow rate and volume will be determined by use of a weir type gaging station. Samples will be drawn at three different elevations by use of a float regulated sampling pipe. Samples will be pumped into containers that are stored within a refrigerator located at the gaging station. Analyses will be made to determine the quantity of major plant nutrients and selected pesticides and herbicides in the runoff water.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0175, DEEP WATER DUMPS
E.A. CHRISTIAN, U.S. Navy, Ordnance Laboratory, *Silver Spring, Maryland* 20910

Technical Objective: Conduct study and exploration on the oceanic pollution impact of munitions disposed of by deep water dump (DWD) operations.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.0176, MICROBIAL DEGRADATION OF ORGANIC POLLUTANTS OF INDUSTRIAL ORIGIN
H.B. GUNNER, Univ. of Massachusetts, School of Agriculture, *Amherst, Massachusetts* 01002

Laboratory and ultimately pilot studies are proposed to establish the basis on which industrial installations may be developed for the removal, by microbiological agents, of toxic organic chemicals prior to effluent discharge into local water courses.

The methods of procedure are as follows: 1. Selection and adaptation of bacteria to specific chemicals in soil profusion columns by primary enrichment of flasks in shake culture and by continuous feed in simulated activated sludge systems. 2. Measurement of chemical degradation, manometrically by means of radioisotope labelling, gas and thin layer chromatography and by autoradiography.

Laboratory data will be employed to provide pilot plant scale units for the controlled degradation of selected organic pollutants.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0177, MICROBIAL INTERVENTION IN THE EUTROPHICATION PROCESS
W. LITSKY, Univ. of Massachusetts, School of Agriculture, *Amherst, Massachusetts* 01002

The objectives of this project are: (1) to relate the microbial decomposition of lake sediments to the release of materials required as nutrient by phytoplankton and (2) to tie-up these nutrient materials in bacterial cells by manipulating the bacterial flora or the aquatic ecosystem.

Further, the purpose of this study is to investigate the processes by which the nutrients that are recycled from the bottom muds are liberated by microbial activity and to find ways whereby these soluble nutrients may be utilized before they become available to algae. In other words competition for the soluble nutrients by a microbial flora other than that involved in the eutrophication process, may be a means of limiting the growth of the undesirable algae species.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0178, THE ROLE OF AQUATIC VASCULAR PLANTS IN THE EUTROPHICATION OF SELECTED LAKES IN WESTERN MASSACHUSETTS
R.B. LIVINGSTON, Univ. of Massachusetts, Graduate School, *Amherst, Massachusetts* 01002

The proposed study will utilize SCUBA gear to obtain quantitative measurements on the productivity (standing crop) of the aquatic vascular plants in oligotrophic and eutrophic lakes in western Massachusetts. The field collections will also add to the record of the aquatic flora of western Massachusetts.

The distribution and abundance of these plants will be correlated with the geological and limnological conditions (pH, temperature, dissolved oxygen, total alkalinity, conductivity and light intensity). The sampling will be carried out in four lakes at monthly (hopefully bi- weekly) intervals.

The seasonal growth of the plants and the nutrient content of their tissues (total nitrogen and phosphorus) will be correlated with the limnological data and particularly the nutrient supplies avail- able in the water and the substrate. This should reveal the presence of any accumulators or indicators of trophic conditions.

Laboratory studies are being carried out on the significance of nutrient absorption by the roots in the metabolism of the aquatic vascular plant.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0179, EUTROPHICATION STUDIES IN BOSTON HARBOR
J.J. COCHRANE, Northeastern University, School of Engineering, *Boston, Massachusetts* 02115

Laboratory studies have been conducted at the Marine Science Institute in Nahant on the growth characteristics of the marine algae, Ulva latissima. In Boston Harbor, specific sites of high Ulva growth have been located, and in the field, changes in water quality and other environmental conditions are being followed to establish a correlation with laboratory results. The information will be used to develop a predictive model for marine algal blooms and their control.

SUPPORTED BY No Formal Support Reported

2.0180, WATER RESOURCES POTENTIAL OF AN URBAN ESTUARY
J.J. COCHRANE, Northeastern University, School of Engineering, *Boston, Massachusetts* 02115

This is an investigation of the physical, chemical and biological parameters pertinent to the development of an urban estuary for recreation and flood control. The specific objectives of the program include: the determination of the effects of nitrogen and phosphorous on the development of estuarine algae, the discovery of the influence of bottom deposits, including nutrients and toxic materials, on the balance of the ecosystem; and finally, the development of improved methodology for the characteriza-

tion of an estuarine environment; this methodology would include mathematical modeling, data collection frequency and analytical techniques.

SUPPORTED BY Massachusetts State Government

2.0181, WATER POLLUTION FROM SANITARY LANDFILLS
W.R. DOMEY, Northeastern University, School of Engineering, *Boston, Massachusetts* 02115

A study of the ground and surface water pollution beneath and near a sanitary landfill has been under investigation in Salem, New Hampshire and Holliston, Mass. This program seeks to correlate the problems involving water pollution which are caused by the solution of problems in solid waste disposal.

SUPPORTED BY Northeastern University

2.0182, BENTHAL DEPOSITS: EFFECTS ON THE QUALITY OF NATURAL WATERS
J. FILLOS, Northeastern University, School of Engineering, *Boston, Massachusetts* 02115

This investigation will study the release mechanism of materials from benthal deposits and determine the release of organics and nutrients that may be expected under natural conditions. An objective of this study will also be to demonstrate the feasibility of controlling the release rate of organics and nutrients through the control of DO levels in the overlying water. The ability to limit releases from benthal deposits by controlling the DO in the bottom waters would indicate a method through which eutrophication can be retarded in natural waterways.

SUPPORTED BY U.S. National Science Foundation

2.0183, GROUND-WATER CONTAMINATION FROM HIGHWAY SALTING IN MASSACHUSETTS
S.J. POLLOCK, U.S. Dept. of the Interior, Geological Survey, *Boston, Massachusetts* 02203

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of Massachusetts.

Purpose: To define the hydrologic principles relating to the movement of highway salt into and through the ground.

Methods: Ground-water sampling stations will be set up in a variety of geologic and hydrologic environments along several major highways. If possible, sites for sampling stations will be selected where previous studies have described a portion of the hydrology and geology of the area. Also, soil samples will be taken from selected depths above the water table at these sites in order to trace the path and rate of movement of the salt both vertically and horizontally.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0184, GROUND-WATER CONTAMINATION FROM HIGHWAY SALTING IN NEW HAMPSHIRE
H.A. WHITCOMB, U.S. Dept. of the Interior, Geological Survey, *Boston, Massachusetts* 02203

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of New Hampshire.

Purpose: To define the hydrologic principles relating to the movement of highway salt into and through the ground.

Methods: Water samples from wells constructed along three major highways and two springs adjacent to two intermediate highways are collected periodically and analyzed. Particle-size analysis of soil samples from the ground-water sampling sites has permitted a comparative evaluation of the permeability of the materials.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0185, STATE-OF-THE-ART STUDY ON CHEMICAL POLLUTION OF FRESH WATER AS A POTENTIAL HUMAN HEALTH HAZARD
T.R. DAVIS, Arthur D. Little Incorporated, *Cambridge, Massachusetts* 02140

Conduct a state-of-the-art study on chemical pollution of fresh water as a potential human health hazard. Examine existing information which has identified chemicals or chemical classes in water and evaluate available data on their individual acute and biological effects which can be used to indicate potential hazards to health. Where the biological effects of identified chemicals are unknown, examine their relationship with chemicals the biological effects of which have been studied and for which a structure-activity relationship has been identified. By this means their potential effects on health can be tentatively predicted. In the course of the work, factors which can be used to arrive at quality criteria for chemicals in water will be evaluated.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0186, NAVY ENVIRONMENT - TRACE ELEMENT DISTRIBUTION IN THE OCEANS & SEA FLOOR SEDIMENTS, THE CONTROLLING BIOCHEMICAL AND PHYSICAL PROCESSES
J.M. EDMOND, Mass. Inst. of Technology, School of Science, *Cambridge, Massachusetts* 02139 (N00014-67 A-0204-0048)

Technical Objective: The potential use of chemical monitoring surveillance systems for the detection and source identification of man- made chemical pollutants will require information on the natural distribution of trace elements in the oceans. This research, which is directed toward determining the biological, chemical, and physical oceanographic processes controlling these distributions, will help provide basic data on natural trace element concentrations in selected oceanic water masses and the understanding necessary for predicting the geographic and time variability of these concentrations.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.0187, RADIOELEMENT STUDIES IN THE OCEANS
V.T. BOWEN, Woods Hole Oceanographic Inst., *Woods Hole, Massachusetts* 02543 (AT(30-1)-2174)

Objective: Clarification of major pathways of geochemical circulation of Sr, Cs, the lanthanides, Sb, Pu in the oceans; estimation of rate of transport; relevant clarification of pathways of atmospheric circulation and of fallout delivery; collection of tracer information on Atlantic Ocean circulation, vertical and horizontal.

Reason: All these sorts of information are needed for prediction of fate of radioactive or other toxic wastes disposed to the atmosphere or seas. Much of this is also pertinent to estimation of how marine productivity may be increased.

Procedure: Radiochemical analyses of fallout or natural nuclides in sea water, over ocean aerosols, marine organisms, sediments and rocks; stable element analyses of such samples by emission spectrometry, activation analysis or wet-chemical methods.

SUPPORTED BY U.S. Atomic Energy Commission

2.0188, MICROBIAL SULFATE REDUCTION AND SULFIDE OXIDATION IN MARINE ENVIRONMENTS
H.W. JANNASCH, Woods Hole Oceanographic Inst., *Woods Hole, Massachusetts* 02543

This grant will continue NSF support of investigations on the sulfur cycle in the marine environment, with emphasis on the role of bacteria on the biological transformation of sulfur compounds. This is a subject of importance to problems of corrosion, anaerobiosis, pollution, and general productivitiy in the sea.

Organisms that have been under study include the sulfate-reducing bacteria, and photosynthetic, purple, sulfide-oxidizing bacteria (Thiorhodaceae). Investigations will now be extended to include the colorless sulfide-oxidizing bacteria. Specific aspects

to be studied include determining (1) morphological and physiological characteristics of the various species of bacteria, (2) the rate of sulfate reduction and sulfide oxidation, and the effect of environmental factors on these processes, (3) enzyme activitiy in different cultures, (4) competition between species, and (5) growth characteristics under controlled environmental conditions.

SUPPORTED BY U.S. National Science Foundation

2.0189, ECOLOGY OF GREAT LAKES ESTUARIES
J.F. CARR, U.S. Dept. of Commerce, Natl. Marine Fisheries Service, *Ann Arbor, Michigan* 48107

The various bays are among the most productive environments of the Great Lakes and they are also the most vulnerable to human activities. Industrial and domestic wastes impair the fertility of the water as well as the edibility of the fish. The immediate objectives of this project are to determine to what extent oceanographic methods can be applied to studies of these bays. Subsequent work will be concerned with the movements and influence on the biota of waters flowing into these areas. Thermal, light transmission, chemical, surface current, sediment, plankton, and benthos data have been collected from Saginaw Bay, Lake Huron. Flushing-rate estimates, using oceanographic methods, have been made for Saginaw Bay. Drogue studies have been made in northern Green Bay, Lake Michigan.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0190, FISH-MERCURY STUDIES IN THE GREAT LAKES
J. CARR, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Ann Arbor, Michigan* 48107

Intensive studies will be undertaken in selected localities of the Great Lakes to determine the distribution and dispersion of mercury in water, aquatic vegetation, fish and waterfowl. Water, sediment, flora and fauna samples will be analyzed for mercury residue. Basic chemical and physical measurements of water, aside from mercury itself, will be routinely made in connection with all samples at the collection site. Research will include the effects of mercury on the food chain organisms and fish and the conversion of inorganic mercury to organic mercury will be traced through the food chain. The acute and chronic toxicity of mercury to several species of fish will be determined.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.0191, A COHERENT-AREA STUDY OF SOUTHERN LAKE MICHIGAN
J.C. AYERS, Univ. of Michigan, Inst. of Science & Technology, *Ann Arbor, Michigan* 48104

The work proposed involves a team-approach to the sedimentary, biological and chemical indications of the eutrophication process in the southern portion of Lake Michigan. This Great Lakes water body is a water resource of present value, and future greater value, within which the effects of man's wastes are becoming evident. The studies would assemble and assess the indications of eutrophic change with the aim of determining the onset of and the present rate of deterioration of water quality.

Related basic studies of the present sedimentary process and present sedimenting materials, along with needed basic studies of the weather-modifying effect of Lake Michigan would also be carried out.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0192, AN IN SITU EVALUATION OF NUTRIENT EFFECTS IN LAKES
M.E. BENDER, Univ. of Michigan, School of Public Health, *Ann Arbor, Michigan* 48104

Species Composition Replicates - Three experiments at Third Sister Lake to correlate or reproduce species changes observed in 1969, which were due to the main effects of chelation, nitrogen and phosphate. These experiments were conducted in April, September, and August; also a fourth experiment in November may be necessary to check on the N x P interaction.

Nutrient Forms - Three 2 x 2 factorial experiments will be conducted in May and June to elucidate the effect of various forms of nitrogen on species response.

An experiment in Crystal Lake during September to replicate the one conducted in 1969, as well as to test other variables (e.g., sewage ligands and trace metals).

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.0193, CHEMICAL TRANSFORMATION, GRAND TRAVERSE BAY, LAKE MICHIGAN
D.C. CHANDLER, Univ. of Michigan, School of Arts, *Ann Arbor, Michigan* 48104

To measure the quality and quantity of chemical inputs to Grand Traverse Bay, to determine the fate of those inputs through the Bay and where they eventually go; and to determine the relative contribution from urban and rural areas.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0194, RAIN SCAVENGING STUDIES
A.N. DINGLE, Univ. of Michigan, School of Engineering, *Ann Arbor, Michigan* 48106 (AT(11-1))

Tracer studies of scavenging processes and convective storm circulations will be pursued in field experiments. Advances in techniques of measuring cosmogenic radioactive species will be investigated with the objective of applying these techniques to the measurement of contaminants in rain samples collected in the field program. Improved definition of the processes of scavenging and the time-scale of cloud processes will be sought. Distributed samples of rain will also be analyzed for their content of air pollution components, particularly lead (Pb) from automotive exhaust fumes, which appears to have peculiarly unfavorable properties for normal air cleaning processes.

SUPPORTED BY U.S. Atomic Energy Commission

2.0195, NUTRIENT CYCLING AND PRODUCTIVITY OF DYSTROPHIC LAKE-BOG SYSTEMS
F.F. HOOPER, Univ. of Michigan, School of Natural Resources, *Ann Arbor, Michigan* 48104 (AT(11-1))

During 1971 we plan to label the mat water of North Gate bog with a P32- rhohamine WT mixture during early spring. We will then follow 1) exchanges of phosporus and iron compounds between the mat and lake water, 2) incorporation of the label into the biota of the epilimnion, and 3) movement of the phosphorus into the hypolimnion via sedimentation and through biological transport by Chaoborus. We propose further studies on the biological conversion of organic phosphorus fractions isolated from the bog mat and from the upper layers of the thermocline using our in situ flow-through system.

We propose more detailed studies on the identification of the complex inorganic phosphorus compounds and the RNA phosphorus fractions from three series of samples at three locations within the basin. We propose to continue studies of the iron cycle by suspending a series of plastic cylinders within the lake that will enclose a core of water from the surface to a depth of 6M. These cylinders will be labeled with Fe59 and the water will then be sampled to measure the dispersion of the lable into various fractions and its movement throughout the water column.

SUPPORTED BY U.S. Atomic Energy Commission

2.0196, NUCLEAR PHYSICS PROGRAM
H.G. BLOSSER, Michigan State University, School of Natural Sciences, *East Lansing, Michigan* 48823

This is a continuation of research sponsored under NSF grant GP- 6760. The accelerator is used in a number of nuclear physics research areas as well as in areas of interdisciplinary research. The nuclear physics program includes transfer reactions where a particle entering a nucleus picks up one or more nucleons. Such reactions are (p,d), (p,t), (p,He3) and (p alpha). These studies give information on the level structure of a nucleus, and permit comparisons with calculations using various theories. Inelastic proton-scattering experiments also contribute information for these studies. Other experiments are performed to gain informa-

tion on the mass of various isospin multiplets and on the nature of this reaction. These involve measurements on various isospin multiplets and analogue states formed by (p,n) reactions. Other charge exchange reactions such as (He3,t) are also studied. Supplementing this information is data obtained through studies of radioactive decay.

In addition to the purely nuclear structure research program, there are studies in progress relating to the nuclear physics aspects of astrophysics, and the application of nuclear technology and results to problems in biology. A recently initiated program applies nuclear technology to the study of environment contamination, for example, the accumulation of mercury in fish.

SUPPORTED BY U.S. National Science Foundation

2.0197, WATERSHED ANALYSIS RELATING TO EUTROPHICATION OF LAKE MICHIGAN
M.E. STEPHENSON, Michigan State University, School of Engineering, *East Lansing, Michigan* 48823

The objectives of the project are to (1) establish a storage and retrieval system of data on water quality and quantity within the surface system of lakes and streams of a major watershed of Lake Michigan, the Grand River, and (2) collect and collate existing data pertaining to the physical, chemical, biological, and socio-economic aspects of the water resources of the basin, (3) incorporate a current evaluation of material transport (phosphorus, nitrogen, total carbon, pesticides, etc.) within the river system, (4) determine the qualitative and quantitative relationships between waste discharge and receiving stream water quality on the Grand River system and Lake Michigan, and (5) carry out a compilation and analysis of land use practices and socio-economic developments as related to each of the water resource parameters considered above.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0198, DISSOLVED ORGANIC MATTER AND LAKE METABOLISM
R.G. WETZEL, Michigan State University, W.K. Kellogg G. Lk. Biol. Sta., *Hickory Corners, Michigan* 49060 (AT(11-1))

Studies are continuing on the qualitative and quantitative analyses of production and utilization of dissolved organic compounds and their role in the nutrition and metabolism of planktonic and sessile producers. Discrimination between bacterial, algal, and macrophytic utilization of organic compounds directly in chemo-organotrophy or indirectly by the complexing of inorganic ions affecting metabolism is being approached experimentally. Both axenic and natural populations are used in distinguishing the significance of the individual mechanisms by which dissolved organic compounds influence photosynthesis at naturally occurring concentrations. Quantitative excretion of dissolved organic matter by sumerged macrophytes, planktonic and epiphytic algae is being studied, both in axenic culture and 'in situ,' with particular emphasis on the relation of such compounds to inorganic nutrition and metabolism. Experimental and 'in situ' analyses of nutritional biotic interactions and cycling on an annual basis are being integrated to develop a quantitative model of predictive capability to permit evaluation of stress parameters leading to eutrophication. Emphasis is being placed on thermal and dissolved organic enrichment.

SUPPORTED BY U.S. Atomic Energy Commission

2.0199, MERCURY IN THE ENVIRONMENT
D.H. KLEIN, Hope College, Undergraduate School, *Holland, Michigan* 49423

The first objective of this project is to define the pathways of mercury from its entry into the environment, through ecosystems, to its final reservoirs. It is not anticipated that sufficient data will be collected during the project period to permit establishment of an accurate environmental mercury budget. The second objective is to investigate the utility of the mercury content of human hair as an index of overall environmental exposure to mercury.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.0200, STUDIES OF COPPER TAILINGS
T.D. WRIGHT, Michigan Technological Univ., School of Science, *Houghton, Michigan* 49931

This project involves basic research on the nature of copper tailings, with the intent of developing information which may be used for vegetative reclamation of the failings. Dr. Erbisch is growing plants experimentally to determine toxicity of the copper tailings. Dr. Kahan is experimenting with growth of blue-green algae to stabilize tailings before the growth of other plants. Dr. Wright is studying the effect of drainage from the tailings on the waters of the lake into which the drainage flows.

SUPPORTED BY Michigan State Government

2.0201, ENVIRONMENTAL FACTORS MODIFYING RADIONUCLIDE CONCENTRATION IN TUBIFICIDAE
C.J. GOODNIGHT, Western Michigan University, School of Liberal Arts, *Kalamazoo, Michigan* 49001 (AT(11-1))

The purpose of the study is to investigate the effect of environmental factors on the physiology of sludge worms (family Tubificidae), particularly as this worm regulates the concentration and retention of radionuclides. Since tubificids are one of the more common bottom dwelling invertebrates in our streams, this will aid in our understanding of the role these worms play in the transmission and concentration of nuclides in food chains which extend from bacteria to man. It will also give us information on environmental effects on concentration and retention of the nuclides among tubificids in a polluted stream.

The isotopes 32P, 45Ca, 89Sr, 43K, 134Cs, 64Cu, 59Fe, and 65Zn will be used in this investigation. All these elements are found normally in the environment and are of biological significance. The regulation and storage of these nuclides in the worms will be measured, using varied concentration of the nuclides in the worm's environment as well as other environmental variables which may influence uptake of the isotopes by this organism. The retention and uptake will be studied under different environmental conditions. The environmental variables to be tested include temperature, pH, concentration of non-radioactive ions in the environment, and type of bottom substrate the organisms live upon. The project was started in 1968 and is expected to be completed in 1973.

Results: Preliminary analysis indicates considerable differences among the several isotopes studied and demonstrates the need for additional data. Observation indicates that temperature affects the metabolism of this organism and results in alteration of the rate of uptake of the isotopes. Also, results indicate that some isotopes such as 32P may be more readily incorporated by tubificids when they are in an organic molecule. Therefore we have been studying the incorporation of these radionuclides in food chains.

2.0202, MEASUREMENT OF PRESENT SEDIMENT LOAD, AND EXPERIMENTAL ADDITION OF SEDIMENT IN TEST SECTION OF HUNT CREEK
D.S. SHETTER, State Res. & Dev. Division, *Lansing, Michigan* 48926

Objectives: To measure present sediment load in Hunt Creek, and to make provision for the addition of more sediment (sand) in a test section of Hunt Creek where its effects will be measured.

Procedures: Collect sediment samples once a week with sampling equipment furnished by Mr. Edward Hansen of the North Central Forest Experiment Station at Cadillac. Mr. Hansen has also agreed to perform the laboratory analyses on these samples. Samples will be collected over the period October 1970 to September 1971, at four or five sites through and below the control and experimental areas. This will entail the placement of three sill logs at sediment sampling sites to accommodate the sediment samples in measurement of bed loads. (2) Install a service road to

the Section A-B line of Hunt Creek by November 1970; excavate a sediment trap at the Z bulkhead for removal of sediment passing through Sections Z and A of Hunt Creek. (3) Introduce measured amounts of sediment into Hunt Creek at the Section A-B line according to instructions to be furnished by Ed Hansen as to amount and periodicity.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0203, EUTROPHICATION - REMOVAL OF NUTRIENTS - SHAGAWA LAKE

L.P. SEYB, U.S. Dept. of the Interior, Federal Water Quality Admin., *Ely, Minnesota* 55731

The objective is to evaluate the removal of algal nutrients from municipal sewage in an advanced waste treatment pilot plant as a means to impede blue-green algal blooms. Nutrient removal will be accomplished by combinations of coagulation, filtration, ion exchange and carbon adsorption operations. Pilot plant effluent will be mixed with lake water in one 125,000 gallon pond immersed in the lake to determine the effect of nutrient removal on algal populations. A similar pond will receive trickling filter effluent mixed with lake water. A third pond will serve as a control. Similar tests will be made in 200 gallon and 5 gallon containers to determine scale effect. Water quality of Shagawa Lake, its inflow, and outflow streams will be determined regularly to establish base-line information.

If nutrient removal by the pilot plant is effective, a full scale tertiary sewage treatment plant for the removal of algal nutrients from Ely's sewage will be considered as a demonstration. Because bottom sediment might be a reservoir for algal nutrients, studies to determine the effect of sediment on the quality of lake water will be undertaken when experimental work in the pond ceases because of weather conditions.

Ultimately, enough facts about algal and aquatic plant growths in Shagawa Lake will be available to provide for a plan to reverse the lake from its eutrophic condition to one that is less or non-eutrophic.

2.0204, IMPROVEMENT AND MAINTENANCE OF WATER TIMING, QUANTITY, AND QUALITY BY MANAGEMENT OF NORTHERN FORESTS

R.R. BAY, U.S. Dept. of Agriculture, North Cen. Forest Expt. Sta., *Grand Rapids, Minnesota* (NC1602)

OBJECTIVE: Develop management practices, through basic hydrologic studies, which will maintain and improve water yield--streamflow timing, water quality, low-flow augmentation, and ground water recharge--on northern forested peatlands.

APPROACH: Gather information on: (1) the hydrology of forested bog watersheds while calibrating experimental watersheds; (2) physical properties and water transmissivity of organic soils; and (3) evapotranspiration rates of bog vegetation. Study effect of timber management and water control practices on: (1) water yield and ground- water recharge; (2) evapotranspiration, water storage, and changes in the properties of organic soils. Determine energy balance regimes in peatlands and other bog-vegetation complexes.

PROGRESS: Measurements of energy relationships on drained and undrained open peatland indicate no difference in net radiation but considerably higher daytime surface temperatures in the drained plot, suggesting decreased evaporation from the sphagnum moss surface when the water table is lowered 12 inches. Land treatments which lower water tables in peat bogs could thus alter the evaporation and runoff regime. Analysis of runoff water from several undisturbed bog watersheds show that the highly acid sphagnum moss surface has a major influence on water chemistry. Total ionic load is low compared to streams draining mineral soil areas. Iron and phosphate levels, however, are relatively high. The data provide a baseline for measuring future changes in water chemistry on the watersheds.

2.0205, HISTORY, EVOLUTION AND EUTROPHICATION OF MINNESOTA LAKES

E. GORHAM, Univ. of Minnesota, School of Biological Sciences, *Minneapolis, Minnesota* 55455

This research will continue the comparative regional studies of aquatic sediments, semi-aquatic peats, and terrestrial soils supported by NSF grants G-23309, GB-2448, and GB-6018, with particular reference to analysis of sediment cores from lakes of several types. Attention will focus upon chemical indices to determine (1) aquatic productivity, past and present, (2) onset of summer anaerobiosis in the hypolimnion, (3) development of eutrophy as marked by abundance of blue-green algae, (4) changes in erosional intensity in the watershed, and (5) changes in water level of shallow lakes. The indices employed may include (1) diversity and concentration of chlorophyll derivatives and carotenoids in sedimentary organic matter, (2) sedimentation rates for organic and carbonate carbon, (3) changes in ratios of iron to manganese, and of organic carbon to sulfur, nitrogen, and phosphorus, and (4) ratios of sodium and potassium to elastic material. These studies will be correlated with regional studies by several members of the Limnological Research Center at this university and by staff of the State Conservation Department.

SUPPORTED BY U.S. National Science Foundation

2.0206, THE ROLE OF MIXING IN MAINTAINING STRATIFIED FLOW

E. SILBERMAN, Univ. of Minnesota, School of Engineering, *Minneapolis, Minnesota* 55414

In controlling pollution of lakes, streams, and beaches, it is desirable to be able to predict the relative importance of stratification and mixing between an effluent and ambient water when there is a difference in density between the two. Density differences may arise, for example, when warm water is discharged into cooler water, when aerated sewage is discharged into normal river water, when fresh water wastes are discharged into salt water, and when sediment-laden water is discharged into clear water. Two somewhat different physical situations are involved; these are the outfall area where effluent and ambient fluid first meet and the area distant from the outfall where persistence of stratification requires study. A broad analytical and experimental study of the problems involved is proposed. The objectives are to improve the ability of the engineer to: (1) determine the degree of stratification that may be expected under given outfall conditions, (2) control stratification and mixing at an outfall, (3) determine the persistence of stratification at a distance from an outfall, (4) determine the effect of wind waves on stratification and mixing, and (5) make model studies of stratification and mixing problems.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0207, ALLEVIATION OF LAKE POLLUTION BY UTILIZATION OF AQUATIC PLANTS FOR NUTRITIONAL, MEDICINAL OR INDUSTRIAL PURPOSES

E.J. STABA, Univ. of Minnesota, School of Pharmacy, *Minneapolis, Minnesota* 55455

The objective of the research is to find a nutritional, medicinal or industrial use for the unwanted aquatic plants in lake shoreline areas. It is possible that some aquatic plants may contain industrially useful gums-mucilages or new useful antimicrobial, anticoagulant, or antineoplastic therapeutic principles. Aquatic plants will be collected from various lakes in Minnesota and identified, processed and phytochemically screened for useful compounds. Microbial and animal studies will be conducted. If a good industrial, medicinal or nutrional use for aquatic plants can be discovered, the results of the research could provide an economic incentive for aquatic plant collection and control. The successful completion of the project might significantly assist the state and Nation in partially solving their lake pollution problems.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0208, DEVELOPMENT OF A MATHEMATICAL MODEL TO PREDICT THE ROLE OF SURFACE RUNOFF AND GROUND WATER FLOW IN OVERFERTILIZATION OF SURFACE WATERS

C.P. STRAUB, Univ. of Minnesota, School of Public Health, *Minneapolis, Minnesota* 55455

Better control of agricultural and natural pollution is required to protect Minnesota intrastate and interstate surface waters. Since nutrient enrichment information is inadequate, studies are planned to develop a mathematical model to predict the role of surface runoff and groundwater flow in the overfertilization of surface waters. Following development of the model, which will include theoretical expressions required for a complete hydrologic budget and general expressions relating to nutrient balance, criteria will be developed for controlling sources contributing to the overfertilization or eutrophication of Minnesota waters. The research effort will identify the primary factors introducing nitrogen and phosphorous to the aquatic environment, will delineate areas where additional data are needed and will evaluate the resultant model under field conditions. The model will assist state and federal agencies in initiating surface water fertilization control programs.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0209, RELATION OF AGRICULTURAL PRACTICES AND NATURAL VEGETATION TO NUTRIENT CONTENT OF WATERS

D.R. TIMMONS, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Morris, Minnesota* 56267 (SWC-027-CMOR-4)

OBJECTIVE: Evaluate the nutrient status of surface runoff from different crops and natural vegetation; determine the influence of different management practices on the nutrient content of runoff water; develop management practices which will minimize the amount of nutrients entering the surface water supply from overland runoff.

APPROACH: Natural rainfall plots will be utilized to study the influence of conventional farming practices on the nutrient content of runoff water. Similar plots will be used to evaluate the nutrient content of runoff water coming from forrested land before and after it passes through a sphagnum peat bog. An artificial rainfall simulator will be used to study the effect of different fertilizer and crop residue management practices on nutrient content of runoff water in an effort to develop practices which will minimize the contribution of runoff from agricultural land to the nutrient enrichment of surface waters.

PROGRESS: Rural land runoff generally contains low concentrations of soluble phosphorus, which is either attached to eroded soil material or in solution in the water. Eroded soil material contains appreciable amounts of phosphorus which is rather rigidly affixed to the eroded soil materials. Thus the quantity reaching surface water supplies and its availability to the biota is not well understood. Phosphatic fertilizer application increases the phosphorus content of the surface soil, which is most vulnerable to erosion. Therefore, practices that incorporate fertilizer phosphorus to greater depths in the surface soil offer promise for minimizing the contribution from fertilizer. Dissolved phosphorus in runoff waters is usually very low; however, under some conditions (leaching of frozen vegetation) appreciable amounts of dissolved phosphorus can enter surface waters. The use of sound soil and water conservation practices, which hold more soil and water on the land, reduce the contribution that rural land runoff makes to the nutrient levels of our lakes and streams. Nutrient enrichment of surface waters is a natural process which cannot be eliminated, but it can be decelerated by judicious application of known soil and water conservation practicies.

SUPPORTED BY U.S. Dept. of Agriculture

2.0210, COOPERATIVE GULF OF MEXICO INVENTORY AND STUDY - III - SEDIMENTOLOGY OF MISSISSIPPI'S ESTUARIES

J.Y. CHRISTMAS, State Marine Conserv. Comm., *Biloxi, Mississippi* 35930

Objectives: (1) To determine the sediment forms of Mississippi estuaries as an index of their respective conditions. (2) To establish a base line for the evaluation of expected changes in sediment distribution and its effect on the biota. (3) To develop an atlas of the sediments of Mississippi estuaries. (4) To make the state atlas available, in cooperation with the other Gulf States and the Bureau of Commercial Fisheries, for inclusion in an atlas of Gulf of Mexico estuaries.

Procedures: (1) Locate and complete existing data for textural analysis (sand, silt and clay) and carbonate, carbon, and nitrogen content in the study area. (2) As time permits, collect and analyze additional samples in a pattern arranged to complete a description of the sediment distribution pattern in the study area. (3) Collect, analyze and prepare data in a state atlas in a form which will be available for incorporation as a section in an atlas of the estuaries of the Gulf States in cooperation with members of the Gulf States Marine Fisheries Commission and the Bureau of Commercial Fisheries. (4) Prepare and publish additional notes and papers as necessary.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.0211, IDENTIFICATION AND ORIGIN OF SEASONAL FOAM IN THE PEARL RIVER RESERVOIR

J.P. MCKEOWN, Millsaps College, Undergraduate School, *Jackson, Mississippi* 39210

Analytical procedures are used to identify the components and source of large quantities of foam which appear periodically on the surface waters of the Pearl River Reservoir. One of the major goals of this investigation is to train undergraduates in procedures used in water analysis and fresh water ecology.

SUPPORTED BY Millsaps College

2.0212, STUDIES ON INORGANIC NUTRIENT ASSIMILATION RATES IN ESTUARINE PONDS

W. ABBOTT, Gulf Coast Research Laboratory, *Ocean Springs, Mississippi* 39564

The captioned research grant has provided funds for construction of 18 estuarine ponds. These ponds are being utilized for field scale testing of hypotheses developed during a series of microcosm studies (Abbott, J. Water Poll. Control Fed., 38:258-270 (1966); 39: 113-122 (1967).

Studies are oriented toward evaluation of phosphorus and nitrogen turnover rates, kinetics of uptake of these elements, and validity of their roles as limiting nutrients in hyperfertilized estuarine situations.

SUPPORTED BY Rockefeller Foundation - New York, N.Y.

2.0213, RESERVOIR SEDIMENTATION

F.E. DENDY, U.S. Dept. of Agriculture, Sedimentation Laboratory, *Oxford, Mississippi* 38655 (SWC-015-BE-2)

OBJECTIVE: Expand knowledge of sedimentation volumes and rates in various type reservoirs. Evaluate reservoir, watershed, and hydrologic factors affecting the deposition rate, density, and areal distribution of sediment and the trap efficiency of reservoirs. Study the physio- chemical aspects of reservoir sediments. Develop instrumentation and techniques to measure significant variables.

APPROACH: Compile and analyze existing reservoir sedimentation data. Isolate and evaluate effects of significant parameters such as capacity-watershed ratio, capacity-inflow ratio, reservoir size and shape, spillway design and operating practices, and watershed and climatic characteristics on reservoir sedimentation and its Properties. Use field and laboratory models. Study sediment bypass and discharge methods.

PROGRESS: A supplement to USDA Miscellaneous Publication 1143, 'Summary of Reservoir Sediment Deposition Surveys Made in the United States Through 1965' was prepared and distributed to various government agencies and individuals. Data recently acquired from reservoirs under cooperative study with the Soil Conservation Service showed a continuation of relatively low sediment deposition rates. Accumulation rates for 13 reservoirs ranged from 0.02 to 3.4 acre feet per square mile of sediment contributing area for periods of from 4 to 14 years. Trap ef-

ficiency ranged from 70 to 93 percent. Soil and reservoir sediment samples were colleted for gamma-ray spectrometric analysis for fallout cesium-137. The concentration of fallout cesium-137 in soils was found to vary with depth in the profile, cover type, and erosion. Cesium-137 was found to a depth of as much as 24 inches in sediments with surface sediments generally less than at a lower depth. The improved dual gamma probe, using the attenuation of transmitted cesium- 137 gamma rays, was shown to operate satisfactorily in estuaries and in small reservoirs for measurement of sediment densities.

SUPPORTED BY U.S. Dept. of Agriculture

2.0214, SEDIMENTATION ON FLOOD PLAINS AND IN ESTUARIES AND HARBORS

S.C. HAPP, U.S. Dept. of Agriculture, Sedimentation Laboratory, *Oxford, Mississippi* 38655 (SWCW1-BE-5)

OBJECTIVE: Extend knowledge of: the amounts, rates and quality of valley sedimentation; the amounts, rates, and causes of channel deposition; the rates, amounts, causes, and location of deposits in valleys, harbors, and estuaries in relation to the flow regimen, basin geometrics, sediment characteristics and other things.

APPROACH: Determine the net effects over a period of 25-30 years of stream and valley sedimentation in selected valleys from a compilation of existing data, resurveys of established cross-sections, and supplemental measurements of selected alluvial fan deposits, streambank and gully erosion, and surveys of selected small reservoirs. Use C-14 dating techniques where appropriate.

PROGRESS: In parts of the Brown Loam hills of north central Mississippi, valley sediment 'plugs', formed at stream channel occlusions, have persisted for more than 30 years of record. Such persistence is due, at least in part, to underlying tough silts which resist headward incision of new or deepened channels below the 'plugs.' These circumstances are largely responsible for deposition of most sediment in headwater parts of creek valleys, 50 that concentrations of suspended sediment carried farther downstream are measured only in hundreds of parts per million, in contrast to thousands of parts per million suggested by generalizations such as Geological Survey Hydrologic Atlas HA-61. Additional data of various kinds, secured during 1967 and 1968, strengthens previous findings that sediment deposits tend to be concentrated in the upper parts of valleys, and that rates of valley sedimentation have declined during the past 30 years both in northern Mississippi and in southeastern Minnesota. The work of dating the loess in the Vicksburg, Mississippi area and the peats in the Florid Everglades and in the Wild Flower Sanctuary Bog of Vermont by the Carbon-14 technique has progressed to the manuscript stage.

SUPPORTED BY U.S. Dept. of Agriculture

2.0215, SEDIMENT SOURCES, YIELD, TRANSPORT, DEPOSITION AND PROPERTIES

L.L. MCDOWELL, U.S. Dept. of Agriculture, Sedimentation Laboratory, *Oxford, Mississippi* 38655 (SWC-014-BE-1)

OBJECTIVE: Determine and predict the magnitude of sediment production, sediment yields from watersheds, the amounts, rates and causes of valley and channel deposition, study all aspects of sediment transport, extend knowledge of physical and chemical attributes of sediment.

APPROACH: Determine by laboratory and field experiments the effect of flow, material and physical conditions on sediment transport; obtain information of physical and chemical properties of sediments by treatments, sampling and analysis. utilize new and existing instrumentation to study sediment yields on watersheds and from models; use modern techniques like remote sensing to relate land use, cover, topography, soils, practices, runoff and other variables to watershed sediment yields; obtain information on rates, amounts, causes, and location of deposits in valleys, harbors and streams in relation to flow regimes, sediment properties and other things.

PROGRESS: During the 1969 water year, sediment and flow data were obtained from 10 complex subwatersheds located in the Pigeon Roost Creek Watershed and one partially urban watershed, Laboratory Creek. Computed gross erosion from watersheds in the Pigeon Roost Creek area is being compared to measured sediment yield. Resurveys show that sediment accumulations have continued in the upper part of the Coldwater River Valley but at a reduced rate since 1940. Overbank sediment accumulation has practically ceased throughout most of the four other Yazoo tributary valleys where channels have been ditched. A similitude analysis of the pertinent variables expressed in the same terms. The sediment concentration profile data have continued to describe log-Gaussian distributions with relative flow depth. Recent tests in an open channel have shown that the variation of the sediment transfer coefficient over the flow depth is not affected by the total amount of material present, as measured by the mean concentration. Concentrations of agrichemicals in solution are frequently higher in the initial runoff from farm lands, but the major portion of the dissolved chemical load is transported at or near the peak water discharge. Significant quantities of plant nutrients such as K, Ca, and Mg were found to be transported in association with sediment.

SUPPORTED BY U.S. Dept. of Agriculture

2.0216, REDISTRIBUTION OF RADIOACTIVE FALLOUT IN WATERSHEDS DUE TO CULTURAL AND EROSIONAL PROCESSES

J.R. MCHENRY, U.S. Dept. of Agriculture, Sedimentation Laboratory, *Oxford, Mississippi* 38655 (AT(49-7))

Radioactive fallout on the earth surface is very likely to be redistributed due to erosion and transport in runoff waters. This study was designed: (1) to review and where necessary improve sampling methodology for accurate determination of radioactivity in soil and in sediment; (2) to measure the levels of radioactivity of sediments in water bodies and compare them with the levels in soils considered the source; and (3) to relate the radioactivity distribution in a containment basin to the fallout frequency and amount in the contributing watershed, its erosional activity and its soil, plant, and hydrologic characteristics. Watersheds in the vicinity of Oxford, Mississippi and throughout the U.S. will be used to provide soil and sediment samples for analysis of cesium-137 concentration as well as bulk density, particle-size distribution C, N, S, and P content, pH, and cation exchange capacity.

Results: Samples for analysis have been collected from 9 States and 24 watersheds for a total of 609 samples. About half of these samples have been analyzed for gamma-ray emissions and spectral data is ready for processing. A preliminary survey of the data from soil samples shows most of fallout cesium-137 is found in the upper one inch where it could be easily removed by erosion. The vertical distribution of cesium-137 in soils under pine forest and oak forest was similar, but under grass cover cesium-137 was found to greater depths. In sediments, concerntration of cesium-137 distribution was variable with lower concentrations in the surface.

SUPPORTED BY U.S. Atomic Energy Commission

2.0217, RATES AND PROCESSES OF RESERVOIR SEDIMENTATION IN THE CORN BELT

H.G. HEINEMANN, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Columbia, Missouri* 65201 (SWC-015-CMO-3)

OBJECTIVE: Relate the rate of sediment accumulation in reservoirs, reservoir trap efficiency, sediment distribution, and volume-weight of reservoir sediment deposits to the influencing watershed, reservoir, and spillway parameters.

APPROACH: Survey selected existing reservoirs in the Corn Belt for accumulation, volume-weight, distribution, and physical and chemical properties of the deposited sediment. Sample and determine the amount of suspended sediment flowing into and out of additional selected reservoirs for trap efficiency determinations on a storm basis. Monitor storage and thermal stratification of these trap efficiency reservoirs. Collect and evaluate the watershed and reservoir parameters which affect the sediment accumulation, volume-weight, distribution, and reservoir trap efficiency. These analyses of field conditions and resultant sedimentation activities provide design criteria for future similar reservoirs.

PROGRESS: At present, we lack useful knowledge on the sedimentation and eutrophication of small reservoirs. Some information exists on sediment yield, but little exists on the processes involved in reservoir sedimentation and eutrophication. Information is sorely needed to optimize reservoir designs for extended usefulness. The object of this research program is to study all the facets of reservoir sedimentation concurrently, in an effort to determine the relationships between its various components. Inflow is evaluated for the following items: runoff rate, sediment concentration and composition, nutrient concentration and composition, and temperature. In the reservoir itself, the movement of the inflow is followed by means of current meters, which give the direction and velocity of the flow and also by water temperature measurements. The nutrient content of reservoir water is analyzed periodically and detailed reservoir sedimentation surveys are made to determine the distribution, volume, and volume-weight of the deposited sediment, as well as its nutrient content, particle-size distribution specific gravity, and other physical dimensions.

SUPPORTED BY U.S. Dept. of Agriculture

2.0218, THE MOVEMENT AND YIELD OF NUTRIENTS FROM AGRICULTURAL WATERSHEDS

H.G. HEINEMANN, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Columbia, Missouri* 65201 (SWC-027-CMO-5)

OBJECTIVE: Determine the rates and forms of nitrogen and phosphorus compounds moving through agricultural watersheds as solutes in runoff and as adsorbed on sediment. Determine how these compounds are affected by storage in the soil matrix and in ground and surface waters.

APPROACH: The nitrogen and phosphorus content in samples of surface and ground waters will be analyzed and compared with fertilizer application rates, numbers of livestock, and other management practices in the study watershed. Behavioral differences in nutrient movement between terraced and unterraced watersheds will be measured. The concentration of nutrients in each sample, along with concurrent stream discharge rates at each gaging station, will be used to compute the rate and amount of nutrients transported from the watershed.

PROGRESS: Dissipation of commercial nitrogen and phosphorus by overland movement and deep percolation for Missouri Valley deep loess soil was initiated in 1969 on four watersheds near Treynor, Iowa. Measurements were made to determine nitrogen and phosphorus content of surface runoff, base flow, tile flow, and ground water. Core samples were obtained to the water table depth to determine soil profile physical and chemical characteristics. Sediment samples were obtained during storm runoff to determine nitrogen and phosphorus content of eroded soil material. Corn production measurements were made to determine yield and mature-plant nutrient uptake. Preliminary results indicate that, although precipitation was slightly above normal, runoff and erosion were low, resulting in negligible discharges of nitrogen and phosphorus from these sources. Base flow discharges of these nutrients were also low. In general, ground water concentrations of nitrogen and phosphorus were low and not affected by fertilizer application in 1969. This study is continuing.

SUPPORTED BY U.S. Dept. of Agriculture

2.0219, CHARACTERIZATION OF ESTERASE(S) PRESENT IN FISH BLOOD

J.W. HOGAN, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Columbia, Missouri* 65201

Initially, a suitable method for collecting uncontaminated fish blood will be selected. The various types of esterase(s) present in different fractions of blood will be characterized. This characterization will probably include such parameters as optimum substrate, optimum substrate level, optimum enzyme level, specific activity, effect of divalent cations, etc. Ideally, at least two species will be studied at the same time so that comparisons can be made. When the basic parameters are known the effect of various anticholinesterase agents will be studied. Initial studies will be in vitro, however, in vivo studies will be incorporated at a later date. In vivo studies will be designed to take advantage of the fact that the effect of a pesticide on individual specimens can be followed in the blood without sacrificing the animal.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0220, ISOTOPES IN THE BIOSPHERE

E.R. GRAHAM, Univ. of Missouri, Agricultural Experiment Sta., *Columbia, Missouri* 65201 (MO00418)

OBJECTIVE: Study the movement of rain-out Sr-90 from surface soil to impounded water systems.

APPROACH: Runoff and erosion experiments of plots contaminated with fission product radioactive nuclides will be continued. It is planned to use I and Ce in addition to Sr on the plots. The plots under study will be continuous bluegrass, corn stover, and wheat stubble. The collected runoff water and soil removed by erosion will be assayed as previously. Some preliminary studies on the effect of nitrogen fertilizers on growth rate of forages and the accompanying effect on the uptake of fission product radionuclides will be undertaken. These will be greenhouse experiments with small grains and legumes.

PROGRESS: Lambs maintained on natural ration with different levels of added cobalt ($CoCl_2$) showed differences in retention of Co cyanocobalomin after intravenous injection of the isotope. Differences in percentage retention of Cobalt by these animals were apparent within day 3 after administration.

SUPPORTED BY U.S. Dept. of Agriculture

2.0221, HEAVY METAL ION INTERACTION AND TRANSPORT WITH SYNTHETIC COMPLEXING AGENTS AND DETERGENT PHOSPHATE SUBSTITUTES IN AQUATIC SYSTEMS

S.E. MANAHAN, Univ. of Missouri, School of Arts, *Columbia, Missouri* 65202

The overall objective is to study transport, reactions and biodegradation of chelates formed from heavy metal ions and synthetic complexing agents, such as proposed detergent phosphate substitutes, in aquatic ecosystems. Initially emphasis will be placed upon citrate ion and ethylenediaminetetraacetate ion.

Specific aspects to be studied are solubilization of metals from metal surfaces by low levels of complexing agents in solution, biodegradation of heavy metal chelates, the influence of synthetic complexing agents upon the leaching of heavy metal ions from sediment deposits, the role of synthetic complexing agents in keeping essential trace metals in solution, thus contributing to algal growth and eutrophication, competition between calcium ions and heavy metal ions for complexing agents and possible methods of heavy metal ion removal from heavy metal chelates.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0222, NITRATES IN WATER SUPPLIES

G.E. SMITH, Univ. of Missouri, School of Engineering, *Columbia, Missouri* 65202

Soils in feed lots of different ages and in various geologic areas are being sampled to depths of 15-25 feet to determine the penetration of nitrate. Included in the sampling are abandoned feeding areas where no livestock have been present for some years. Samples are also collected on transects at different distances from the area of contamination (both feed lots and sewage disposal systems) to determine lateral movement. Movement is being correlated with soil physical properties.

Detailed soil samples are being collected and topographic maps are being prepared of areas where new feed lots are being built. This information will serve as a basis for measuring changes that occur in the surrounding soil areas in the future.

Accumulation of residual nitrate from chemical fertilizers is being measured at locations where detailed soil fertility studies are being conducted with varying rates of nitrogen fertilization. Samples of soil, to depths of 10-20 feet, are also being made on individual farms where accurate records of heavy fertilization with nitrogen are available for 10 to 15 years. These results are compared with adjacent areas that have no nitrogen.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0223, NITRATES IN PLANTS AND WATER SUPPLIES FROM NITROGEN FERTILIZATION
G.E. SMITH, Univ. of Missouri, Agricultural Experiment Sta., *Columbia, Missouri* 65201 (MO00485)

OBJECTIVE: Study the effect of N, P, K and trace element fertilization on the accumulation of nitrates in forages and vegetables. Investigate the effect of species and plant age on nitrate reduction in plants and the accumulation of other nitrogen fractions. Survey the nitrate content of domestic and livestock water supplies in the state and determine the influence of watershed fertilization on nitrate content of runoff.

APPROACH: Forages and vegetables will be grown in the greenhouse under different nitrogen fertilizer treatments and samples collected at different stages of growth for analysis. Surveys will be made of surface water supplies and shallow wells in the different areas of the state where high nitrates have been found. Effort will be made to find the source of contamination.

PROGRESS: Where 120 lbs. of N in chemical fertilizer per acre have been applied annually for 20 years to corn on Mexico silt loam, nitrate has been found to a depth of 9 feet. Total nitrate accumulation during this 20 year period was 180 lbs. per acre-9 lbs. per acre- per year, (corn yields averaged 85 bu/A.) This amount is insignificant as a pollutant of groundwater for animals, but this quantity entering surface water could stimulate eutrophication. Nitrate accumulation on far soils of different texture after 7 years with different rates of fertilization show that annual nitrogen addition should be no greater than crop removal. Generally, where annual nitrogen application was 100 lbs. per acre or less there has been little nitrate accumulation. With heavier amounts there was sufficient carry-over to be of concern in water pollution. On sandy soils nitrogen not absorbed by crops entered groundwater supplies. Further studies of nitrates under feed lost showed penetration was associated with soil type and length of operation. In most cases nitrate concentration dropped to low levels from 300-500 feet from fences.

2.0224, GEOLOGICAL FACTORS RELATING TO SURFACE AND GROUNDWATER POLLUTION
J.H. WILLIAMS, State Geol. Survey & Wa. Reso., *Rolla, Missouri* 65401

Agency carries out, as a part of its routine work, continuing investigation of the geological factors that allow the contamination of groundwater, streams, and impoundments. Much of this work is done in cooperation with the State Divison of Health and the State Water Pollution Board. Problems of site selections for sewage lagoons, pollution of groundwater by contaminants introduced through sinkholes and caves, and well construction problems in karst terrains are physical ones. Publication of results of studies is made as time and circumstances permit.

SUPPORTED BY Missouri State Government

2.0225, SALT POLLUTION OF GROUNDWATER
N. AHMED, Univ. of Missouri, School of Engineering, *Rolla, Missouri* 65401

The proposed research plan involves a laboratory study of the movement of a salt water body under the influence of suction gradients. Salt water with different concentrations will be used in the lower part of a parallel plate model. Fresh water will be used in the upper part of the model. Fresh water will be drawn out under the suction head and movement of salt water will be observed. It is anticipated that results of this study will be useful to understand the phenomena of flow of salt water in groundwater reservoirs.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rcn.

2.0226, THE IMPACT OF LEAD-ZINC MINING ON THE QUALITY AND ECOLOGY OF SURFACE WATERS IN SOUTHEAST MISSOURI
E.A. BOLTER, Univ. of Missouri, Water Resources Research Ctr., *Rolla, Missouri* 65401

A study is proposed to investigate the impact of Lead-Zinc mining activity on the quality and ecology of surface waters in the 'New Lead Belt' of SE Missouri. The study area now has little population and industry, but intensive mining activity will develop during the next few years.

During the investigation, the background values for lead, zinc, copper, iron, silver and cadmium in unpolluted surface waters, sediments and aquatic life samples will be determined. After pollution has started, the self-cleaning capacity of the streams by precipitation or adsorption of the metals and the uptake of the metals by aquatic life will be determined. The analyses will be done with an atomic absorption spectrophotometer.

2.0227, INVESTIGATION OF PRESENT THERMAL REGIME OF MISSOURI RIVER IN MISSOURI
J.C. MAXWELL, Univ. of Missouri, Water Resources Research Ctr., *Rolla, Missouri* 65401

The proposed research is to characterize the present thermal regime of the Missouri River between Kansas City and St. Louis, Missouri for the seasons of the year. This will include temperature variations with depth and across the width of the Missouri, and development of a mathematical method of analyzing a fluctuating temperature so as to detect a non-fluctuating change of a few degrees such as might be introduced by nuclear or fossil fuel power plants. A secondary objective is to determine the feasibility of using thermal characteristics and remote sensing aerial infrared imagery to trace possible polluted masses of water as they progress down the Missouri.

Little is known about present distribution of temperature in these rivers. An opportunity is now available to determine the background thermal base for these rivers which may be lost within two or three years as large power plants are installed along the rivers and thermal pollution is introduced. These data could be most significant in assessing effects on life forms as water temperature conditions change in the future.

A remote-reading Quartz thermometer will be used which will permit measurements accurate to 0.05 degrees C, and a program will be developed for the IBM 360 Mod 50 computer to analyze the available records.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0228, EVALUATION OF SUBSURFACE MOVEMENT OF LEACHATES PRODUCED FROM SANITARY LANDFILLS
J.D. ROCKAWAY, Univ. of Missouri, School of Mines, *Rolla, Missouri* 65401

To evaluate the movement through the ground-water regimen of leachates produced from sanitary landfills, and to determine the influence of various soil materials in controlling or retarding leachate movement.

Several sample sites in characteristic Missouri soil types have been selected for study, with respect to operation and procedures of development, ground-water regimen, geologic setting, and the nature and extent of dissolved-solids concentrations. Statistical modeling is to be applied to the data on leachate movement and subsurface conditions to provide a quantitative evaluation of the influence environmental conditions have in controlling groundwater pollution derived from sanitary landfills.

SUPPORTED BY University of Missouri

2.0229, STREAM SEDIMENT INVESTIGATION
P. MARCUSON, State Fish & Game Department, *Billings, Montana* 59101

Good trout populations in a stream depend upon suitable water quality. The 'Stream Sediment Investigation' to date on Bluewater Creek proved that agricultural siltation all but eliminated the trout population.

A pilot project on Bluewater Creek is proposed to demonstrate methods to improve land-use practices which cause agricultural-silt pollution. The effect of the reduction in silt pollution on the trout population will be evaluated.

Methods to be used in controlling siltation are lining irrigation return ditches, encouraging more efficient use of irrigation water and streambank fencing to protect streambank vegetation from livestock damage. A dense growth of trees, shrubs and grasses can become established, controlling lateral bank erosion. Areas to be fenced will be leased by the Fish and Game Department for a minimum of ten years to encourage cooperation with the individual landowners.

Effects of the improved land-use practices will be evaluated at five permanent sampling stations located along Bluewater Creek starting at a clean-water station.

Sediment samples analyzed by the U. S. Geological Survey will provide sediment concentrations and water quality at the sampling stations.

Fish populations of the stream within the sample areas will be sampled periodically with electrofishing gear.

Quantitative and qualitative bottom fauna information will be obtained from the permanent stations.

Water temperatures and flows will be recorded at the sampling stations.

Man-made redds placed in Vibert boxes in the sample areas will test trout-egg survival under various sediment concentrations. The Mark VI standpipe apparatus will be used to measure the rate of deterioration in apparent velocity and intragravel oxygen concentrations in the man-made redds under various sediment concentrations.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0230, WATER RESOURCES IN SOURDOUGH AND MIDDLE CREEK WATERSHEDS - A COMPARATIVE STUDY OF QUALITY AND HYDROLOGY
R.L. SANKS, Montana State University, School of Engineering, *Bozeman, Montana* 59715

Bozeman Creek (or Sourdough) and Middle Creek watersheds are two adjacent drainages of 39.8 and 48.2 square miles respectively, located about 10 miles south of Bozeman, Montana. The two watersheds are rather similar in size, elevation, and topography, but entirely different as to land use. Since 1917 Bozeman Creek watershed has been closed to public use, since it is one of the sources of water for the city of Bozeman. Hyalite (or Middle Creek) has always been open and has been widely used for grazing and recreation. There has been some logging on each watershed. There is currently much pressure to have Bozeman Creek watershed opened to the public. A target date of August 1968 was set for opening. Water samples which have been collected from selected points on both watersheds since 1964 have shown that Bozeman Creek consistently has higher counts of microorganisms than does Hyalite Creek.

The present study has been inaugurated to provide answers to the question of whether Bozeman Creek and similar watersheds which are used for municipal water supply should remain closed to human use, to pinpoint areas of potential erosion and sedimentation problems and to evaluate the severity of erosion and sedimentation on the watersheds, and to determine some knowledge of the basic hydrology of the watersheds, which will aid in planning studies on these, and on similar watersheds throughout the Pacific-Northwestern United States.

Hydrologic data to be collected includes information from a series of raingages, weather stations and streamflow recorders on each watershed. Water quality data to be collected includes pH, suspended and dissolved solids, and concentrations of various ions from selected sampling stations on both watersheds.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0231, CYANIDE METABOLISM BY MICROORGANISMS
G.A. STROBEL, Montana State University, School of Letters, *Bozeman, Montana* 59715

During the past five years various aspects of cyanide production and utilization by microorganisms have been investigated. It has been shown in all cases that the first product of active (enzymatic) cyanide fixation is a nitrile. In many cases the nitrile is an alpha-amino nitrile which in turn is hydrolyzed to the corresponding alpha-amino acid. The proposed research would investigate and compare enzymes capable of hydrolyzing these alpha-amino nitriles to their corresponding amino acids.

In the fungi, ammonia and cyanide condense with aldehydes to yield the alpha-amino nitrile. The work proposed in this research project would clarify the origin of these aldehydes in the fungus mycelium.

Investigations on additional pathways of cyanide utilization in other microorganisms will be continued. Work on cyanide metabolism should be of benefit to people interested in the following scientific areas: water pollution, cyanide is one of the top ten pollutants of fresh water streams, metabolic biology, cyanide is a commonly used inhibitor of respiration, soil microbiology, cyanide as a contributor to the C and N cycles in nature, and, prebiotic chemistry, cyanide as a prebiotic gas on the earth's surface.

SUPPORTED BY U.S. National Science Foundation

2.0232, AN INVESTIGATION OF THE EXTENT AND CAUSE OF EUTROPHICATION OF CANYON FERRY RESERVOIR, MONTANA
J.C. WRIGHT, Montana State University, School of Letters, *Bozeman, Montana* 59715

There are indications that Canyon Ferry Reservoir, Montana, a main stem impoundment of the Missouri River has become more eutrophic since its impoundment in 1953. Increased severity of blue-green algal blooms and deterioration of water quality are cited as evidence. Agricultural pollution has been blamed for the situation.

It is proposed to prepare a nutrient budget for the reservoir by sampling nutrient input from the river, nutrient input from irrigated agricultural, nutrient storage and output from the reservoir.

Standing crops of phytoplankton and zooplankton and concurrent concentrations of available phosphorus and nitrogen will be determined. These will be compared with similar baseline data gathered in 1956-1959.

On the basis of this data it will be determined if the reservoir has become more eutrophic and if so, what is the cause and source of the excessive nutrients.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0233, THE LIMNOLOGY OF YELLOWTAIL RESERVOIR AND THE BIG HORN RIVER
J.C. WRIGHT, Montana State University, Graduate School, *Bozeman, Montana* 59715

An investigation will be made of the physical, chemical and biological limnology of Yellowtail Reservoir, Montana and Wyoming and its downstream effect if the Big Horn River. The cycle of events in the reservoir will be related to the water regime which involves deep water discharge and the creation of internal density currents. The effect of this regime on the heat budget, salinity budget, and the nutrient budget will be compared with the effects that could be expected from surface water withdrawals. The downstream effects of nutrient- rich cold water discharge will be related to the productivity, benthic algal production and the heat budget of the Big Horn River. The population dynamics of zooplankton will be followed over a period of five years in order to determine if changes occur that could explain the decreasing productivity of reservoirs following their initial high productivity. Changes in the zooplankton populations will be correlated with reciprocal changes in the phytoplankton population which in turn will be related to nutrient, temperature and light conditions. The

areal hypolimnetic oxygen deficit of the dead storage zone of the reservoir will be used as an index of the overall productivity of the reservoir, over a period of five years. The project started July, 1969 and it is anticipated that it will be finished January 31, 1972.

2.0234, NATURAL WATER SYSTEMS IN WESTERN MONTANA

A.R. GAUFIN, Univ. of Montana, Graduate School, *Missoula, Montana* 59801

The principal objective of the program is to determine the water quality of aquatic systems west of the continental divide. These parameters which constitute criteria for the quality of water in a particular system are being analyzed. The biota and chemical and physical characteristics of the water are being studied to provide criteria as to the quality of water and degree of pollution in various drainage systems throughout the region.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0235, SILTATION RATES AND LIFE EXPECTANCIES OF SMALL HEADWATER RESERVOIRS IN MONTANA

R.L. KONIZESKI, Univ. of Montana, School of Forestry, *Missoula, Montana* 59801

Increased emphasis must be placed on the silting and building of small, headwater reservoirs in Montana. A major problem is the present inability to predict life expectancies of such structures. Principal siltation controls are apparently geological, topographic, climatological and vegetational. The immediate objectives of this study are to: categorize the most common 'type' watersheds, select sample reservoirs, define environmental controls, and describe siltation rates. The ultimate objective is to devise procedures to make accurate predictions of life expectancies of proposed headwater reservoirs. Additional objectives are to determine the effects of environmental controls on the water chemistry, and to determine possible radioactive contamination from nuclear fallout.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0236, INVESTIGATION OF THE EUTROPHICATION PROCESS OF LAKE MCCONAUGHY, WESTERN NEBRASKA

N. STUCKY, State Game & Parks Commission, *Lincoln, Nebraska* 68509

Objective: Design a comprehensive study to determine the rate of nutrient enrichment of Lake McConaughy.

Procedures: 1. Conduct an extensive review of literature pertaining to the eutrophication process. 2. Examine other investigations which have been and are presently being performed on Lake McConaughy by other agencies and institution 3. Determine which water quality parameters will best depict the rate of eutrophication of Lake McConaughy. 4. Conduct preliminary sampling to determine the sample size necessary for each parameter to detect a change over a given period of time which is statistically significant. 5. Design a study to determine the rate of nutrient enrichment of Lake McConaughy.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0237, POLLUTION OF SURFACE AND GROUND-WATER RESOURCES

D.M. EDWARDS, Univ. of Nebraska, Agricultural Experiment Sta., *Lincoln, Nebraska* 68508 (NEB-11-023)

OBJECTIVE: Quantitatively and qualitatively study, in the laboratory and in the field, different components of potential contamination to water and the effect of these constituents on changing soil and water characteristics. Specific objectives are: evaluate the effects different agricultural chemicals and wastes may have upon surface and subsurface waters, determine what effect contaminated water supplies have upon the characteristics of the soil, devise improved and/or new methods of water pollution prevention and control, train graduate and undergraduate students for research in the area of water pollution, supply, treatment, and quality as related to agricultural production and rural and urban water supplies and sanitation.

APPROACH: Laboratory and field studies will be conducted to determine the level and type of natural and artificial water contamination, objective 1. This information will be compiled and evaluated to allow building to simulated laboratory models. The models will be used for qualitative studies of the basic parameters of these waters and their effect upon soil conditions, as well as upon surface and subsurface water pollution, objectives 2 and 3. Finally, the information gathered from the laboratory studies will be used initially in the laboratory, and, if promising there, in the field for improved and/or new methods of water reuse and pollution prevention and/or control, objective 4. Radiological and electrokinetic techniques of electrophoresis, streaming potential, and electroosmosis will be extensively used for the study.

PROGRESS: The studies of applying nitrogen fertilizer to surface irrigation tests areas consisted of mechanical application and in the irrigation water. Results were initial run-off contains most nitrates, little or no loss of nitrates from within the soil, and proper irrigation management can minimize nitrate losses in run-off and deep percolation waters. A study completed was the influence of electrokinetic potentials upon the development of incrustation and corrosion on water well screens. A study completed was the feasibility of using chemicals to clarify runoff waters from beef feedlots using Zeta-potential techniques. A study underway is the feasibility of sub-surface irrigation in the Northern Great Plains. This would reduce the needed size of water source, and control the amount and placement of potential pollutants.

2.0238, EUTROPHICATION OF SMALL RESERVOIRS IN THE GREAT PLAINS

M.J. HAMMER, Univ. of Nebraska, School of Engineering, *Lincoln, Nebraska* 68508

Very little is known about eutrophication in small reservoirs and virtually nothing is known about the eutrophication of Nebraska's waters. What species of algae are present (including indicator organisms) in what quantity, and how does this quantity change with time? What is the present level of eutrophy in existing small reservoirs? What are the nutrient levels and nutrient sources, and what is the existing water quality? Answers to these questions are presently unavailable.

The proposed research is to gain information on reservoir eutrophication by studying flood control reservoirs constructed near Lincoln, Nebraska, in the Salt Valley Watershed District. The four reservoirs included in this study are well suited for this research since their ages vary from one to six years and their sizes range from 100 to 1800 acres of water surface.

The specific objectives of the proposed research are: 1. To determine the present trophic condition in selected reservoirs in the Salt Valley Watershed by monitoring several biological and physio- chemical parameters, to determine the rate of eutrophication in these reservoirs by observing changes in the above parameters over a three year period, and to evaluate the future usefulness of these reservoirs for recreation. 2. To identify sources of nutrient input into these reservoirs, both agricultural and domestic. 3. Based on the data collected from these studies, to evaluate preventive and remedial measures to improve water quality and retard the rate of eutrophication.

2.0239, SOILS, PESTICIDES AND THE QUALITY OF WATER

T.L. LAVY, Univ. of Nebraska, Agricultural Experiment Sta., *Lincoln, Nebraska* 68508 (NEB-12-071)

OBJECTIVE: Identify and characterize the physical-chemical properties of the pesticide-soil-water system which are pertinent to (i) pesticide transport through the soil in infiltrating water, and (ii) pesticide desorption from eroded soil into surface waters. Determine the kinetics and degradation mechanism of picloram and identify the principal degradation products.

APPROACH: The effect of soil properties such as base saturation, soil type, pH, and temperature on the mobility of pesticides in soil columns will be studied. The degree of pesticide adsorption which occurs when various amounts of water are added to the soil in the columns will be measured by assaying sections of the column for the pesticide or its degradation product(s). Nutrient uptake by plants growing in soil-water systems may be altered by an accumulation of the mobile pesticide around the plant roots. The degradation rate of picloram and other mobile pesticides positioned at various soil depths will be evaluated using chemical and bioassay methods. The use of 14(C) labeled pesticides and liquid scintillation counting will permit the detection of trace amounts of pesticide. Extent of degradation of the parent molecule will be assayed using thin layer and gas liquid chromatographic techniques.

PROGRESS: Atrazine was degraded 2 to 3 times faster in topsoils than in subsoils. Each 10 C temperature rise from 15 C to 35 C caused the degradation rate to increase 2 to 3 times. Pesticides will be deactivated more rapidly if they do not move below the surface six inches. Dissipation of dicamba was greater in Sharpsburg silty clay loam soil than in lighter textured low organic matter, Anselmo sandy loam soil. Degradation occurred more rapidly at 35 C than 15 C. Dicamba was most phytotoxic to corn seedlings at pH 4. Although dicamba was taken up by both roots and shoots, root uptake caused greater growth reduction. In laboratory studies the acid form of amiben was more mobile in soils than the ester form which was adsorbed more strongly. This adsorption appears to be closely associated with soil organic matter. Root uptake was more important than shoot uptake. Amiben derivatives which were not susceptible to leaching in laboratory studies provided poor weed control with excessive rainfall.

SUPPORTED BY U.S. Dept. of Agriculture

2.0240. SOIL AND WATER MANAGEMENT SYSTEMS FOR PREVENTION OF SOIL AND WATER POLLUTION
T.M. MCCALLA, Univ. of Nebraska, Agricultural Experiment Sta., *Lincoln, Nebraska* 68508 (SWCW8-DLI-4)

OBJECTIVE: Measure the magnitude of and develop soil and water management systems for the prevention of pollution of soil, surface and ground waters by harmful nutrients, organic wastes, and toxic chemicals arising from various kinds of land use in subhumid areas, including land use for livestock feeding, industrial and municipal waste disposal.

APPROACH: Laboratory and field investigations, often on a watershed basis, will be conducted to study the movement and decomposition of nutrients, agricultural chemicals and organic waste resulting from different kinds of agricultural land use, with emphasis on concentrated live-stock feeding in feeding in relation to water balance investigations where runoff, evaporation, percolation, rate and direction of groundwater movement are measured.

PROGRESS: Highest solubility and suspensibility of cattle feedlot manure was found on samples collected near feedlot bunkers. Appreciable numbers of organisms regarded as pollution indicators were present. These remained suspended after 24 hours of settling, and the nitrate and inorganic phosphate remained in solution. Decomposition studies on manure over a three-month period, wetted with urine simulating stocking rates of 50 and 250 square feet per animal, showed 80 to 90% loss of the nitrogen as ammonia, loss of 50% of the volatile solids, little nitrification, and complete destruction of the E. coli and Enterococci. More washoff of solids occurred on 13 than on 8% slopes using simulated rainfall, but there was no difference in runoff. Loss of solids from a 13% feedlot slope was less than from a conventionally planted cornfield on the same slope. Studies on a flat feedlot where no manure is hauled away show little runoff, accumulation of pollutants in the profile with both aerobic and anaerobic decomposition occurring, and high concentrations of organic pollutants in the surface of the water table. On a sloping loess hills feedlot site, 12 inches of the 26 inches of annual precipitation ran off. Runoff was high in solids, total phosphorous and nitrogen, and microorganisms. Aeration in the profile is good and nitrification occurs. Nitrate in the surface of the water table was higher than under surrounding cultivated fields.

SUPPORTED BY U.S. Dept. of Agriculture

2.0241. ASSESSMENT AND CONTROL OF POLLUTION OF SURFACE AND GROUND WATER BY FERTILIZERS
T.M. MCCALLA, Univ. of Nebraska, U.S.D.A. Soil & Wa. Cons. Div., *Lincoln, Nebraska* 68503 (SWC-027-DLI-3)

OBJECTIVE: Assess the hazard of eutrophication of surface and ground water by deep percolation, runoff, and sediment transport of nitrogen, nitrate and phosphate from fertilizers applied to crop and grassland in the subhumid loess hills in Iowa and Nebraska.

APPROACH: Measurements of downward and surface movement of phosphorus, nitrogen and nitrate will be made on instrumented watersheds treated with recommended and excessive rates of fertilizer on contour planted continuous corn, corn on a benched watershed, and a bromegrass meadow at Treynor, Iowa. Samples of runoff, sediment and spring flow, and samples obtained by periodic core drilling will be analyzed and calculations of amounts made from data on water flow and sediment transport. Additional core drilling will be done in Nebraska for fuller assessment of the potential hazard from overuse of fertilizers. Laboratory chemical studies will be made on sediment, core and soil samples for better interpretation of the field data.

PROGRESS: Laboratory analysis of samples of base flow and runoff water and of sediment from the differentially fertilized watersheds at Treynor, Iowa showed no seasonal changes in nitrogen or phosphate concentration of baseflow or concentration changes that could be related to recommended vs. extremely high rates of fertilization of corn. Soluble phosphate in runoff is greatly reduced by the adsorption of phosphate by sediment in eroding gullies. Relatively high concentrations of ammonia are found in runoff water from snowmelt. Nitrate concentrations in deep cores were extremely variable and often high on watersheds with a long history of corn production. High rates of nitrogen fertilization have not changed nitrate concentrations in profiles significantly, but the sampling variation is so great that possible differences cannot be detected.

SUPPORTED BY U.S. Dept. of Agriculture

2.0242. WATER AND SOIL POLLUTION FROM BEEF CATTLE FEEDLOTS IN NEBRASKA
T.M. MCCALLA, Univ. of Nebraska, Agricultural Experiment Sta., *Lincoln, Nebraska* 68508 (NEB-12-074)

OBJECTIVE: To determine amounts and characteristics of pollutants being deposited on, in runoff from, in soil profile, and in ground water of beef cattle feedlots, and to determine microbial decomposition patterns of animal wastes.

APPROACH: Select typical feedlot sites; instrument sites for measuring runoff and determining water table depth; collect feed, urine, and runoff samples from sites and ground water; make laboratory determinations of pH, fecal coliform, total counts, and routinely total P, N, and COD, and other selective determinations as deemed necessary.

PROGRESS: The runoff from beef cattle feedlots at the University of Nebraska Field Laboratory, Mead, resulting from rainstorms and snowmelt, is highly variable, both in the quantity of runoff and the concentration of materials. Feedlot slope and density of stocking did not appear to affect the total material resulting from rainstorms. In 1969, winter runoff from 130 ft/animal lots yielded an average of 4.5 times more total solids than from 200 ft/animal lots. An estimated 6% of the volatile solids deposited on the feedlot surface was transported in runoff for lots with stocking rate of 200 ft/head and 3% with stocking rates of 100 ft. If winter runoff is included, the corresponding percentage values are 14 and 26.8. Results of 1-year study indicate that the movement of pollutants under research feedlots has been minimal, however, there was a buildup of nitrates in profiles adjacent to the feedlots. On a flat, river-bottom feedlot that had not been cleaned since 1956, nitrate-nitrogen in feedlot ground water samples exceeded the Public Health water standards on only 3 occasions in 2 years. The hazard was minimal as these levels were detectable only for a short time after the initiation of irrigation pumping. In the soil, the low oxygen level, low oxidation-reduction reading, and the organic layer buildup appear to be responsible for the low nitrate levels. Data indicate that surface conditions and stocking rate both affect the pollution potential of a feedlot.

2. WATER QUALITY

2.0244, DISSOLVED CONSTITUENTS OF NATURAL WATERS - CONTRIBUTIONS FROM MINERALIZED AREAS
J.V SHARP, Univ. of Nevada, Desert Research Institute, *Reno, Nevada* 89507

Geologic terranes where ore metals and substances occur in abundance relative to usual occurrence are possible sources of unusually high concentrations of trace and certain gross constituents in natural waters. These constituents may be harmful for human consumption or for agricultural or industrial use. Ground and surface waters are sampled from selected mineralized districts and surrounding areas and analyzed for gross and trace constituents. Spatial and temporal occurrence of dissolved constituents is related to sources in mineralized rock and mine and mill disposals. Transport of consituents is interpreted in light of hydrodynamic and geochemical characteristics of flow systems. Results are related to water utilization, particularly cases where deleterious constituents may be a limiting factor on water use.

Phase II involves completion of studies in silicate geologic terranes and of acid mine drainage.

2.0245, DETERMINATION OF THE STAGES OF EUTROPHICATION OF SOME OF NEW HAMPSHIRES LARGE LAKES PHASE II
P.J. SAWYER, Univ. of New Hampshire, Graduate School, *Durham, New Hampshire* 03824

The determination of the stages of eutrophication has been carried out on only one of New Hampshire's lakes, it is proposed to extend this knowledge. Five lakes will be investigated, one of them in two different places. Attempts will be made to gather information on the chemical, physical, and biological characteristics of the lake. The chemical characteristics to be determined will be oxygen, carbon dioxide, alkalinity, phosphates, nitrates, and possibly some ionic determination by atomic spectroscopy. Physical characteristics to be identified will be pH, light penetration, temperature stratification, and conductivity. Finally, primary productivity will be measured by the carbon-14 technique, and the zooplankton and phytoplankton components will be identified. Additional work will be done on the impact of copper sulfate on lake communities.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0246, AN INVESTIGATION OF APHANIZOMENON FLOS-AQUAE, A TOXIC BY-PRODUCT OF EUTROPHICATION
P.J. SAWYER, Univ. of New Hampshire, Graduate School, *Durham, New Hampshire* 03824

An investigation of the toxicity of Aphanizomenon flos-aquae, is proposed. The project is divided into three parts. Part I, to be executed by Prof. Ikawa, will be an attempt to isolate and identify chemically the endotoxin found in the algae. Part II, under Dr. Sasner's direction, will be a study of the physiological effects of the toxin at the cellular level particularly among the excitable tissues. Part III, to be accomplished by Dr. Sawyer, will be a study of the effects of the toxin on members of the aquatic communities associated with eutrophic lakes.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0247, ABNORMAL TRACE METALS IN CARDIOVASCULAR DISEASE
H.A. SCHROEDER, Dartmouth College, School of Medicine, *Hanover, New Hampshire* 03755

Environmental exposures of man to selenium, molybdenum, chronium and strontium have been ascertained by analyses of a large number of foods, waters, human and animal tissues. Age linked changes in human tissue concentrations of molybdenum, chromium and strontium have been ascertained. Total body burden of selenium was calculated at 14 mg.

Mice have been exposed for life from weaning time to low concentrations of selenite, selenate, tellurite, tellurate, scandium, gallium, yttrium, indium, rhodium, palladium in drinking water. Selenium, rhodium and palladium were carcinogenic.

Rats have been simularly exposed to selenate, tellurite, molybdate, zirconium, niobium, antimony, vanadium, lead. Selenate was carcinogenic, antimony was toxic in terms of survival. Chromium deficiency was associated with aortic plaques, elevated serum cholesterol and fasting glucose. Manganese deficiency was associated with hyperglycemia, which was antagonized by copper. Elevated serum cholesterol was produced by white sugar; it was depressed when brown sugar was given.

Toxicities of airborne metallic pollutants were evaluated.

2.0248, BIODEGRADATION OF OIL SLICKS IN THE MARINE ENVIRONMENT
R. BARTHA, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00504)

OBJECTIVE: Determine the rate natural biodegradation of oil slicks in various marine environments; to identify predominant degradation pathways, intermediary products and their biological activity to evaluate currently used emergency measures as to their effect on the ultimate biodegradation of the polluting oil; and to develop new techniques for accelerating the biodegradation of oil slick in the marine environment.

APPROACH: A 'model petroleum' will be used in laboratory test with sea water, beach sand and sediments added. Hydrocarbon degradation will be monitored by periodic sampling and gas chromatograph. Oxygen consumed or carbon dioxide produced will be measured. Pure cultures of marine microorganisms will be used in studies of degradation pathways. Detergents used to clean up oil slicks in emergency situations will be tested for effects on biodegradation of crude oil and of model petroleum in laboratory and field studies. Results of these studies will be used to develop new techniques for accelerating the biodegradation of oil slicks.

PROGRESS: To find ways for prediction and improvement of biodegradation rates of polluting oil in the sea, in the first year of the project water and sediment samples were collected from polluted and nonpolluted marine environment. Enrichment with various hydrocarbons and hydrocarbon mixtures yielded several cultures of hydrocarbon- degrading marine bacteria, actinomycetes and fungi. Media consisting of natural or amended seawater supplemented with representative hydrocarbon mixtures of known composition were tested under controlled incubation conditions for their suitability as a model system for the quantitative measurement of oil biodegradation in the sea. For the same purpose, conditions of qualitative and quantitative analysis of the representative hydrocarbon mixtures by gas chromatography were developed.

SUPPORTED BY New Jersey State Government - Trenton

2.0249, HYDRODYNAMICS AND DISCHARGE MEASUREMENTS OF STORM SEWERS
E.L. BOURODIMOS, Rutgers the State University, School of Engineering, *New Brunswick, New Jersey* 08903

This research project will be carried out through three major procedures and converging steps to a central objective: (a) Hydrologic and Hydrodynamic Analysis: Mathematical modeling and theoretical analysis of spatially varied unsteady (or steady) sewer flow. (b) Laboratory Experimental Study: use of tracer techniques in the field and in the laboratory will be attempted in order to verify the analytical predictions of the study. The theoretical analysis will contribute in understanding of the mechanism of flow while the field work will provide the practical objectives of the project. (c) Field work: measurement of storm sewer flow and comparison of actual data with the theoretical and experimental predictions of the study.

2.0250, THE POTENTIAL CONTRIBUTION OF FERTILIZERS TO WATER POLLUTION

L.A. DOUGLAS, Rutgers the State University, Agricultural Experiment Sta., *New Brunswick, New Jersey* 08903 (NJ00037)

OBJECTIVE. Determine the ultimate distribution of fertilizer materials after fertilizers are added to the soil, with specific concern to ground and runoff water and to develop a model for predicting the ultimate distribution and subject it to field testing.

APPROACH: Fertilizers will be applied to controlled field plots. The movement of the fertilizer will be monitored by collecting soil water at various depths, runoff and soil material eroded from the plots. Fertilizer materials recovered from the plots by leaching, runoff and erosion will be determined and related to soil properties. A model will be developed from the data for the purpose of predicting such distributions from applied fertilizers.

PROGRESS: This study was initiated on July 1, 1969, with the principal objective of evaluating the contribution of fertilizer nitrogen and phosphorous to water pollution. This first season was devoted to: leaching nitrogen from an experimental site, and developing field sampling and analytical techiques. The turf was removed from the plots and the plots planted to Sudan grass in July. Sampling of soil water and runoff was started. The NO(3) contents of the soil water varied between 5 and 250 ppm NO(3). The higher values were obtained after several rain-free, warm days, followed by a good rain. Apparently the wetting front contained a high level of NO(3), contrasted with low NO(3) levels a short distance behind the wetting front. In September soil water NO(3) values dropped to below 5 ppm. No PO(4) values greater than 1 ppm were observed.

2.0251, URBANIZATION AND ITS EFFECT ON WATER RESOURCES

M. MARCUS, Rutgers the State University, Graduate School, *New Brunswick, New Jersey* 08903

The proposed research is intended to identify, describe, and project major processes of urbanization in relation to land use and water pollution aspects of water resource development. The study will define urbanization in terms of industry and households as the two major urban water user groups.

Dr. Marcus proposes to analyze the aggregate area (New Jersey) economy as a set of industries in which urbanization characteristics can be examined and for which projections can be attempted. Existing industry, employment and population data will be used. The analysis will be organized to describe anticipated changes in the economic dimensions of newly urbanized areas and project industrial growth into the future.

Test projections of increased population and densities will be made for periods of 10 to 20 years in duration, based upon state projections of county populations.

Gen. Whipple and Dr. Yu have studied the development of the new organic pollution load over a period of years in three key watersheds, i.e., the Millstone-Stony Brook, The Raritan, and the Passaic. These results have shown that a large proportion of organic pollution comes from sources other than effluents. A statistical analysis and correlation is being carried out to determine the relationship between growth of pollution load on one hand and growth of population and of specific types of industry on the other. These projections to determine what growth of raw organic pollution load may be expected in key river basins of the state up to the year 2000.

2.0252, MOSQUITO CONTROL - TIDAL MARSHES

F. FERRIGNO, State Div. of Fish & Game, *Trenton, New Jersey* 08625

Objectives: Chemical and physical evaluation to provide adequate control of mosquitoes on tidal marshes. Also, to evaluate their effects on other marsh organisms as well as the water, soil, and other interests.

Procedures: Over the years this study has supplied us with much information on the problems associated with coastal mosquito - wildlife management interests. Studies to be undertaken pertaining to transporting and building up of residual insecticides on marshes or within marsh organisms. Accordingly, it is urgent that an organization equipped with facilities to determine the chemical analyses of water, soil, salt bay eggs, micro and macro-organisms, and tissues, cooperate in the study. Every effort should be made this year to determine the 'hidden effects' of these chemicals in this environment. In addition, experimentation will continue on open marsh water management in an effort to provide long-lasting control of mosquitoes and a better environment for fish and other wildlife. Ponding and ditching will be evaluated.

This study will eventually lead to control of pestifereous insects, improvement of the tidal food web, and eventually elimination of insecticide from tidal marshes. Over 2000 acres of heavy mosquito breeding marshes have been controlled by open marsh water management.

Chemicals are no longer needed on these areas and organisms of the food web are increasing.

2.0253, SOIL AND WATER MANAGEMENT FOR SALINITY CONTROL - PHASE II

P.J. WIERENGA, New Mexico State University, School of Agriculture, *Las Cruces, New Mexico* 83001 (C-2165)

Saline soils constitute a large fraction of irrigated soils in the western United States and in other irrigated areas throughout the world. The conventional method for controlling soil salinity is to leach soils by applying large amounts of water. This process is a costly use of water, and contributes furthermore to salt pollution of groundwater supplies and to high salt levels in drainage water. Recent studies indicate that soil profiles may be leached more efficiently by applying smaller quantities of water.

The proposed study involves use of large, well instrumented lysimeters to determine the magnitude and nature of soluble salt movement under unsaturated soil water conditions. During each of several irrigation treatments continuous measurements will be made of the soil temperature, the soil-water content, the salt content, the composition of the soil extract and the concentration and composition of the leachate. Treatments will consist of irrigating with various quantities of irrigation water differing in salt concentration and ionic composition. The movement of nitrogen, phosphorus and pesticides will be studied in homogeneous and stratified soil profiles. The data obtained from the lysimeters will be used as input datas for a computer simulation program for predicting salt movement under unsaturated flow conditions. Comparisons will be made between observed and computed rates of salt movement under various irrigation regimes.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0254, POLLUTION STUDIES OF THE REGIONAL OGALLALA AQUIFER AT PORTALES, NEW MEXICO

R.G. TAYLOR, Eastern New Mexico University, School of Liberal Arts, *Portales, New Mexico* 88130

Preliminary investigations have demonstrated the presence of bacterial organisms of fecal pollution in the aquifer at Portales. It is proposed to examine the aquifer in both the chemical and bacterial parameters and extend observations to elucidate any possible seasonal variations. Bacterial examination is proposed by use of Millipore filtration, analyzing for fecal coliforms, total coliforms, Pseudomonas and total bacterial numbers. Chemical analyses of aquifer water will include nitrate, organophosphate, sodium, calcium , magnesium, total hardness and pH employing

Standard Method's procedures. Identification of any seasonal variations in either the chemical or bacterial parameters will permit elucidation of the pollution source as to its possible origin coming from recharge.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0255, MORPHOLOGY AND STABILITY OF STREAM CHANNELS IN SOUTHWESTERN SEMIARID RANGELANDS

J.C. DRISSEL, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Santa Rosa, New Mexico* 88435 (SWCW2-GSR-2)

OBJECTIVE: Methods for predicting and control of gully and stream channel erosion, and sediment deposition damage.

APPROACH: Evaluate processes of channel aggradation, degradation, horizontal realignment, and changes in cross-sectional shape and net sediment yield in relation to types of bed and bank materials, upstream sediment sources, streamflow regimes and control measures.

PROGRESS: Channel scour at seven study sites selected and instrumented with vertical ropes attached to an anchor. Scour on individual flows is highly variable and related to peak discharge. Bed found to scour during early portion of hydrograph and refill on recession and varied from 6 inches to 4 feet. Headcuts and bank scour and sloughing are major sources of sediment in this watershed. Bed material samples collected at visible changes in stratification in vertical sections have been correlated with peak discharges. Coarse material at stratification change is overlaid with successively finer layer deposited on hydrograph recessions. Coarsest material probably represents scour depth for particular flow.

SUPPORTED BY U.S. Dept. of Agriculture

2.0256, CANADARAGO LAKE EUTROPHICATION STUDY

L.J. HETLING, State Dept. of Env. Conserv., *Albany, New York* 12205

The nature and courses of eutrophication of lakes is being studied. A detailed study is being made on Canadarago Lake, Otsego County, New York. Data collection and sampling on the lake began in May, 1968, in order to establish its physical, hydrological, chemical, and biological characteristics. From this basic data more specific engineering control mechanisms such as advanced waste treatment, improved individual summer home waste disposal methods, agricultural practices, diversion of land run-off, etc., will be evaluated. A nutrient balance has been constructed and the temporal and spatial variations in nutrient loading to the lake have been determined. A modern sewage treatment facility for Richfield Springs capable of nutrient removal is planned for construction in late 1971.

The objectives of the 1971-72 FY are: 1. Determine the relationship of land use to nutrient land run-off, and attempt to control nutrient run-off by land use practices. 2. Determine the dynamic effect of nutrient reduction at the sewage treatment plant and subsequently by land run-off control on the lake's. 3. Develop a model relating the lake's eutrophic state to man's activities which could be used in lake management.

To accomplish the above, continual surveillance of the biological, chemical and hydrological system over the next several years is planned as well as several specific studies.

SUPPORTED BY New York State Government - Albany

2.0257, MECHANISM FOR THE CONCENTRATION OF BACTERIA IN JET AND FILM DROPS

D.C. BLANCHARD, State University of New York, School of Arts, *Albany, New York* 12224

Research by Professor Blanchard has found that bubbles breaking at the surface of water which has been inoculated with bacteria Serratia marcescens eject jet drops into the air whose concentration of bacteria is 10 to 1000 times that of the water in which the bubbles burst. This suggests that high concentrations of bacteria are to be found in the surface microlayer. A part of this layer is skimmed off by the bursting bubble and ejected into the air. Not only do bacteria concentrate at the bulk water surface but they have been found to concentrate at the surface of the bubble as it rises through the water. A bubble aging tube will be used to investigate the increase in bacterial concentration on jet drops as a function of bubble age. The bacteria concentration in film drops will also be studied. A final aspect of the research is a study of the concentration of airborne bacteria upwind and downwind of bubbling regions (waterfalls, etc.) in polluted bodies of water.

SUPPORTED BY U.S. National Science Foundation

2.0258, BUFFALO RIVER OIL POLLUTION PROGRAM

R.C. ZIEGLER, Cornell Aeronautical Lab. Inc., *Buffalo, New York* 14221

The Buffalo River Project is a two-phase program for preventing and eliminating oil pollution of the Buffalo River. Phase I is concerned with specifying oil containment and removal equipment which includes air barriers, surface booms, debris catchers, and skimmers, both portable and fixed. This phase also provides for evaluation of performance and cost analysis of operation of this equipment under various climate and flow conditions. Sampling and analysis techniques to determine quantities and types of oil present will be developed. Phase II is a development and evaluation of instrumentation to detect oil in a sewer system. Methods will also be investigated to prevent oil from entering the River at times of sewer overflow.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0259, INVESTIGATION OF THE MERCURY POLLUTION OF LAKE ERIE AND ITS AQUATIC LIFE

K.K. PILLAY, Western N.Y. Nucl. Res. Center *Buffalo, New York* 14214

A program of investigation to provide an insight into the factors involved in the mercury contamination of lake Erie and its aquatic life is proposed.

The field studies will investigate the existing mercury levels in water, sediment, plankton/algae and fish and the variation in the levels over the proposed five-year period of the study. The sampling points have been selected to provide a clear understanding of the distribution and variation with time of mercury in the three basins of the lake. The mercury concentrations in three species of fish - Walleyes (a non- migratory predator), Coho Salmon (a migratory predator) and Channel Catfish (a non-migratory non-predator) - will be investigated.

The laboratory study will investigate the effects of mercury on the development, growth rate and viability of the three fish being considered in the field studies and the mechanism involved in the metabolism of mercury in these fish. The metabolic studies will include investigation of the uptake, release, sequestration and concentration of mercury.

The results of the studies will be used to predict the future course of mercury contamination in water, fish and aquatic life of the lake.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0260, TRIBUTARY SUPVEY OF LAKES ONTARIO AND ERIE

W.A. PEARCE, State Conservation Department, *Cape Vincent, New York* 13618

Objective: Obtain information on Lake Ontario and Lake Erie tributaries required for an anadromous fish management program.

Procedures: Project personnel will review existing stream data. Streams needing more data will be selected for detailed surveys. Study streams will be mapped for use in identifying areas of special need. A suitable stream survey sheet will be designed that will complement existing forms in use by other agencies such as lamprey control units.

Survey schedules will coordinate with other agencies working on individual streams including lamprey control surveys in May or June, Regional Fish Management surveys, spawning run checks. Study streams must be checked during critical periods of high and low flow, winter ice conditions, times of high water tem-

peratures and irregular flows from hydro-power plant controls. Individual plans for each of the important streams and tributaries include: 1. General physical and chemical data. 2. Barrier sites - both permanent and temporary. 3. Existing and potential salmonid spawning and nursery sites. 4. Potential spawning channel, rearing pond, weir and fish ladder sites. 5. Acquisition needs. 6. Sources of pollution. 7. Regulated flow recommendations where applicable.

An overall tributary plan encompassing individual stream plans will be completed for Lake Ontario. A similar plan will be completed for New York's section of Lake Erie.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish

2.0261, KINETICS OF MICROBIOLOGICALLY MEDIATED TRANSFORMATIONS OF HEAVY METALS IN AQUATIC ENVIRONMENTS

A.W. LAWRENCE, Cornell University, School of Engineering, *Ithaca, New York* 14850

The objective of this project is to investigate the fate of heavy metals in the aquatic environment for the purpose of developing qauntative models for engineering management of water quality. Mercury, a heavy metal which is the subject of intensive current interest will be studied first. Its use as a model of heavy metal behavior will be considered. Subsequent study of other metals such as zinc will follow procedures developed in the mercury studies.

The proposed project will consist of: 1) a thorough review of the literature on the fate of mercury and other heavy metals in the aquatic environment (lakes and estuaries), 2) a laboratory study of the kinetics of microbially mediated transformations of mercury including the effects of pH, temperature, and organic carbon concentration, on these kinetics, 3) literature review and laboratory investigations of the role of microbially mediated sulfide production in the distribution and relative avalability of mercury and other metals, and 4) development of a mathematical model to describe microbially mediated transformations and subsequent distribution of mercury and other heavy metals in the water column and benthos.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0262, EUTROPHICATION TIDAL WATERS

J.P. BARLOW, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00588)

OBJECTIVE: To determine the effects of nutrients on the growth of estuarine phytoplankton.

APPROACH: This will be done by placing natural phytoplankton populations under various experimental conditions in which the effect of light, nutrients, etc. on rate of photosynthesis may be determined.

PROGRESS: No Progress Reported This Period (Active Project).

SUPPORTED BY New York State Government - Albany

2.0263, EUTROPHICATION IN WATER RESOURCES OF NEW YORK STATE

J.P. BARLOW, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00805)

OBJECTIVE: To determine the nutrients that limit major components of the existing plankton population in Lake Cayuga and probable effect of additional nutrients on the growth and composition of this population.

APPROACH: Environmental conditions will be described by bi-monthly samplings at several depths to determine plankton abundance and concentration of plant nutrients, phosphorous, nitrogen, silicon, potassium, and other factors such as transparency and temperature.

PROGRESS: No progress reported this period (Active project).

SUPPORTED BY New York State Government - Albany

2.0264, MICROBIOLOGY AND WATER QUALITY IN A TRIBUTARY OF CAYUGA LAKE

N.C. DONDERO, State University of New York, School of Agriculture, *Ithaca, New York* 14850

The effect of a large cattle feedlot on the quality of the water of a tributary to Cayuga Lake, N. Y., will be studied. Microorganisms and microbial growth factors stimulatory to algae are expected to be abundant. Samples for microbiological assay for biotin, thiamin, and cyanocobalamin will be collected. The basic chemical and physical parameters of pollution and eutrophication will be ascertained as well as bacteriological parameters. Samples will be taken weekly below and above the feed lot and at six other stations along the stream. Analyses will be made for the following: dissolved oxygen, biochemical oxygen demand, chemical oxygen demand, conductivity, alkalinity, Kjeldahl nitrogen, nitrates, ammonia, phosphate, pH, total solids, total plate counts, coliforms, fecal coliforms, streptococci, Salmonella, and nitrifying and denitrifying bacteria.

The data will be shared with others working on invertebrates and periphyton of the stream and those working on the water quality of Cayuga Lake.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0265, LIMNOLOGICAL INVESTIGATION OF ONEIDA LAKE

D.J. HALL, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00110)

OBJECTIVE: Investigate current nutrient conditions in Oneida Lake in light of possible nutrient enrichment. Examine relationship between continuous nutrient recycling and plankton production. Determine the fate of the zooplankton in Oneida Lake.

APPROACH: A two-year study is proposed in which extensive year- round water analyses, quantitative plankton and fish collections will be made in order to ascertain fundamental relationships in the food chain dynamics of Oneida Lake. Analyses of phosphorous, nitrogen and other selected nutrients will be routinely carried out. The rate of nutrient regeneration will be examined in relation to the unusual summer circulation (mixing) pattern in the Lake. The primary production of phytoplankton using the C-14 technique and zooplankton population turnover rates will be estimated from appropriate field experiments and analyses.

PROGRESS: The entire year has been devoted to data analysis (counts, computations and graph construction) and manuscript preparation. Pre-final results indicate striking numerical and size effects of fish predation (Yellow Perch) upon Daphnia populations.

SUPPORTED BY U.S. Dept. of Agriculture

2.0266, EFFECTS OF EUTROPHICATION ON AQUATIC VEGETATION - PHASE II

H.F. MULLIGAN, State University of New York, School of Agriculture, *Ithaca, New York* 14850

This project involves the study of the effects of enrichment with ammonium, nitrate, and calcium monobasic phosphate hydrate on the growth of plankton algae and selected species of aquatic weeds in twenty, 1/10 acre experimental ponds. The aquatic weeds are being studied in the ponds include Elodea canadensis, Potamogeton crispus, and Myriophyllum spicatum var. exalbescens. Enrichment replications have been established in these ponds during the summers of 1968 and 1969. In the summer of 1970, no fertilizer will be added and bi-monthly estimates of the rates of growth of plankton algae and bottom weeds will be obtained. The species composition and succession of plankton algae and records of bottom weed populations will be noted.

In this way, effects of prior fertilization or species diversity and density of plankton algae and bottom weeds can be evaluated. Residual effects of nutrient enrichment on the entire aquatic ecosystem will be estimated by measuring nutrient composition of the soil and water on a bi-monthly basis.

2. WATER QUALITY

These data will be summarized so as to provide information on the ecological consequence resulting from a reduction or cessation in nutrient enrichment to surface waters.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0267, EUTROPHICATION AS A PROBLEM IN THE FINGER LAKES
R.T. OGLESBY, State University of New York, School of Agriculture, *Ithaca, New York* 14850

Existing data will be combined with a limited summer sampling program to define the state of eutrophication of the Finger Lakes of New York. Transparency, chlorophyll, phytoplankton, nitrates, phosphates, dissolved oxygen, pH, and alkalinity measurements will be compared for the lakes and nutrient analyses will be performed on the principle tributaries. Together with a consideration of land use patterns, basin morphometry and lake flushing times, these observations will be used to develop hypotheses to account for the observed production levels. A more comprehensive study will be designed to verify the postulates thus generated.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0268, LOSS OF ORGANIC AND INORGANIC MATERIALS FROM ABOVE-GROUND PLANT PARTS BY LEACHING
H.B. TUKEY, State University of New York, School of Agriculture, *Ithaca, New York* 14850 (AT(30-1))

Appreciable quantities of inorganic and organic metabolites, including growth regulators, are leached from above-ground plant parts by rain, mist, fog, and dew. Mineral nutrients, amino acids, organic acids, and carbohydrates are leached from a wide range of plant species. Young plants, including economically important food crops, are grown in radioactive nutrient solutions that are leached with a water mist. The leachates are collected on resins and the losses by leaching are determined quantitatively by radioactive analysis, and qualitatively by chromatographic, photometric, and bioassay techniques.

Important areas of investigation are, 1. effect of leaching upon flowering, 2. effect of leaching upon leaf senescence and dormancy, 3. involvement of leaching phenomena in chemical ecology, that is plant/plant chemical interactions, 4. influence of leaching in environmental quality, as a method of decontamination from certain pollutants, and as a method of dispersal of environmental pollutants.

Results: Leaching is influenced by species, metabolites being leached, leaf morphology and age, nutrition, and environmental factors. Substances leached from one plant can be utilized by other nearby species. Leaching is an important ecological factor in plant development, and it plays a role in the distribution of contaminants.

SUPPORTED BY U.S. Atomic Energy Commission

2.0269, AGRICULTURAL CONTRIBUTIONS TO NUTRIENTS IN WATER
P.J. ZWERMAN, State University of New York, Agricultural Experiment Sta., *Ithaca, New York* 14850 (NYC00342)

OBJECTIVE: Determine the effects of selected farming practices on the forms and amounts of nutrients contributed to water and determine the availability of the different forms to aquatic plants.

APPROACH: Runoff and tile flow from 24 0.8-acre plots receiving differential fertilization, manuring, and management will be measured and sampled. Particulate matter will be separated, and both soluble and particulate material will be analyzed for nutrients. A portable rainfall simulator will be used to create runoff from other differentially treated areas to be similarly analyzed. Algae and bottom-rooting plants will be grown in greenhouse environments to evaluate availability of nutrients in organic extracts from farm manure, soil organic matter, and in particulate matter from the field experiment described above.

PROGRESS: Two separate experimental fields are being utilized. One is a relatively long-time study of nutrient losses under high and low fertilization. 1000K(2)O/A is applied on all plots. High fertilization receives in addition, 2000N and 1000P(2)O(5) per acre. Low fertilization receives approximately 1/3 of these amounts. Tile drainage waters contained 9.5 and 24.5 mg/l NO(3) expressed as N under low and high fertilization respectively. This condition existed where some vegetative cover was growing in early April. In 'clean cultivated' corn in July, the corresponding numbers were 40.4 and 153.5 mg/l. A second experimental area was studied from a former crop rotation experiment terminated in 1968. A 'rainmaker' was utilized to study runoff and erosion rates. Infiltration rates were 20% greater following 10 years in a rotation of wheat-4 years of alfalfa than following other rotations or continuous corn. On plots cropped continuously to corn, manure at a rate of 6T/A/yr increased infiltration rate 20%.

SUPPORTED BY U.S. Dept. of Agriculture

2.0270, STRONTIUM-90 FALLOUT OVER THE OCEAN
H.L. VOLCHOK, U.S. Atomic Energy Commission, Health & Safety Laboratory, *New York, New York* 10014

Ocean water samples collected by the Woods Hole Oceanographic Institution are analyzed for Sr-90 under AEC contracts administered by HASL. The data are used for ocean circulation studies. Most of the samples are collected at four Coast Guard Weather Stations in the North Atlantic.

Four Coast Guardship stations are equipped to sample fallout over three-week periods. Data from this project allow estimates to be made of total fallout delivery to the sea surface and the source of seawater to be traced at specific locations.

A stationary platform has been erected 25 miles northwest of Andros Island 12 feet above the shallow water on the Great Bahama Banks. Fallout collectors and rain gauges have been mounted on the platform to measure the Sr-90 deposition rate. Seawater samples are collected monthly in the Gulf Stream and near the platform.

Results: Both the amount of precipitation and the total Sr-90 in the rain are lower at the platform on the Bahama Banks than at nearby land stations. Available results suggest that isolation of the Bahama Bank water takes place in the first half of each year and that the water is gradually mixed with the open ocean in the seond half.

SUPPORTED BY U.S. Atomic Energy Commission

2.0271, SEASONAL VARIATIONS OF SOME LIMNOLOGICAL FACTORS IN LITTLE SODUS BAY, NEW YORK
G. ENGEL, State University of New York, Graduate School, *Oswego, New York* 13126

The southern shoreline of Lake Ontario is interrupted by numerous small to large size bays. The openings of these bays into Lake Ontario are regulated by wave action of the lake or by dredging operations and breakwaters. Little Sodus Bay is located in the northwest corner of Cayaugo County and covers approximately 630 acres. With the Town of Fair Haven at its southern end, the bay provides a recreational facility and protected area for small boats and fisherman. Little is known about the biological productivity of this and similar bays on Lake Ontario, about physical and chemical factors that determine the productivity, or about the possible effect of the productivity of these shallow bays on Lake Ontario as an aquatic environment.

Thus it is proposed to study the protected waters of Little Sodus Bay to determine the seasonal variations of biological productivity and an analysis of the causitive factors. The data will provide an illustration of a special eutrophic situation and the possible influence of pollution from the surrounding area. The collected information will also be useful when studies on the adjacent open lake are undertaken. Because we lack a suitable research vessel at the present time, limnological investigations initiated by the field biology station must be carried out in protected waters.

Samples (from different locations and depths will be analyzed for dissolved oxygen, carbon dioxide, hardness, alkalinity, pH, phosphates, nitrates, and total dissolved solids) will be taken once every two weeks during the open water season and monthly when there is an ice cover. Physical factors of light transmittance, temperature (air and water), wind, current and turbidity will be observed.

SUPPORTED BY State University of New York - Albany

2.0272, EXTENT OF LAKE ONTARIO POLLUTION CAUSED BY THE OSWEGO RIVER
R. ENGEL, State University of New York, Graduate School, *Oswego, New York* 13126

It is proposed to undertake a short term study to determine the feasibility of a pollution investigation of the Oswego River where it flows into Lake Ontario. The extent of the effect on Lake Ontario would be determined by the dilution rate which in turn is regulated by several factors which may fluctuate daily.

By determining the distribution of benthic organisms at the mouth of the river it is possible to eliminate the effects of fluctuations of river discharge. The numbers and kinds of benthic organisms can be compared to known pollution tollerant and pollution sensitive forms.

Once it is known that this can be done, the information will be used in application for outside support from the U.S. Army Corps of Engineers or the Federal Water Pollution Control Administration.

This project is being carried on under the auspices of the Lake Ontario Environmental Laboratory (LOTEL) of the State University College at Oswego.

SUPPORTED BY State University of New York - Albany

2.0273, MOLECULAR INTERACTIONS AT THE OIL-WATER INTERFACE AND THE FORMATION OF MICROEMULSIONS
D.O. SHAH, Columbia University, Graduate School, *Palisades, New York* 10964

1) Studies on molecular interactions at the oil/water interface and the formation of oil-in-water or water-in-oil microemulsions have been of a great interest in relation to water pollution by detergents and oils, as well as to disasters such as the wreckage of an oil tanker. 2) New techniques will be devised in this investigator's laboratory to study molecular interactions at the oil-water interface by measuring various parameters such as interfacial tension, potential, and viscosity. 3) Influence of the following factors on formation of microemulsions will be studied: the nature and concentration of various electrolytes present in sea-water; the structure and chain length of various hydrocarbons; the structure and surface charge of various anionic, cationic, and nonionic detergents. 4) The molecular interactions governing the formation of microemulsions will be deduced from parallel studies on mixed monolayers at oil-water interface. 5) The mobility of hydrocarbon chains and water molecules in these microemulsions will be investigated by using nuclear magnetic resonance spectroscopy, and the structure of microemulsions will be studied by optical and electron microscopy.

2.0274, ALGAL POPULATIONS RELATED TO WATER QUALITY IN LAKE CHAMPLAIN
G.K. GRUENDLING, State University of New York, School of Arts, *Plattsburgh, New York* 12901

The project involves studies of the species composition, periodicity, and abundance of phytoplankton populations of selected areas of Lake Champlain and measurement of related physical and chemical parameters. Special emphasis is being placed upon the evaluation of stations near populated centers and areas which receive runoff from large rivers. These are being compared with the results obtained from stations in the deep, open portion of the lake. In addition to the identification and enumeration of phytoplankton populations, the seasonal and vertical distributions of nitrate, silicate, phosphate, total phosphorus, calcium, potassium, magnesium, sodium, and selected trace metals are being determined.

SUPPORTED BY State University of New York - Albany

2.0275, CONTROL OF POLLUTION FROM OUTBOARD ENGINES EXHAUST: A RECONNAISSANCE STUDY
W.W. SHUSTER, Rensselaer Polytechnic Inst., School of Engineering, *Troy, New York* 12181

A reconnaissance study will be made to determine the extent of pollution which results from the operation of a two-cycle outboard engine. It is proposed to investigate the effectiveness of a pollution control device in alleviating the impact of exhaust products upon a water system.

The study will entail the development of sampling and analytical techniques for the evaluation of exhaust products evolved. The studies will be conducted in a tank with timed increments of engine operation producing a variety of oil contamination in the water. Tests will be made both with and without the pollution control device on the engine. Analyses of the products will be accomplished with gas chromatographic techniques as well as thin layer chromatography. These analyses will be supplemented by a technique utilizing piezoelectric quartz crystal resonators currently being used on oil studies.

Investigations will be performed on the presence and abundance of hydro-carbon bacteria as an indicator of the extent of self-purification of the exhaust products by indigenous bacteria.

With the development of this initial information it should be possible to estimate the potentials of pollution from two cycle outboard engines.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0276, MODIFICATION OF CHRONIC MANGANESE POISONING
G.C. COTZIAS, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The aim of this project is to discover the means by which the hitherto irreversible neurological picture can be ameliorated in chronic manganese poisoning. These aims are being pursued in collaborative studies between Brookhaven National Laboratory and Catholic University of Santiago, Chile.

Results: It appears that L-Dopa is even better in the treatment of chronic manganese poisoning than it is for Parkinson's disease. Patients suffering from the dystonic or the Parkinsonian-like pictures of chronic manganese poisoning have remarkably benefited with regard to all symptoms except the dysarthria which did not respond. One individual who become worse on L-Dopa improved on 5-hydroxytryptophane. The therapeutic effects were well sustained with passing months. They were maintained diurnally throughout each day.

Animal investigations are being conducted in support of these studies.

SUPPORTED BY U.S. Atomic Energy Commission

2.0277, ENVIRONMENTAL BIOLOGY - BIOGEOCHEMICAL CYCLING IN ECOLOGICAL SYSTEMS
G.M. WOODWELL, Brookhaven Natl. Lab., *Upton, New York* 11973 (AT(30-2)GEN-16)

The objective is measuremet of the total inventory and rates of flux of nutrient elements through both terrestrial and certain aquatic ecosystems of Long Island. Studies have included an inventory of DDT residues in a Long Island estuary. One of the principal tools in the measurement of nutrient flux in the forest is a lysimeter plate, capable of collecting water that would normally percolate into the water table. Studies with these plates have shown that a forest has mechanisms for retaining nutrient elements; these mechanisms break down under irradiation and other disturbances. Nutrients lost in this way to the water table contribute to the eutrophication of the estuarine bays along the South Shore of Long Island.

Results: Data are now available on the total inventory of nutrients in the forest, inputs in precipitation and certain data on losses of nutrients into the water table.

SUPPORTED BY U.S. Atomic Energy Commission

2.0278, DISTRIBUTION OF RADIONUCLIDES IN A SERIES OF OCEAN WATER PROFILES AND SURFACE WATER STATIONS IN THE SOUTH PACIFIC OCEAN
T. RAFTER, New Zeal. Dept. Sci. Ind. Res., *Lower Hutt, New Zealand*

2. WATER QUALITY

Investigation of the distribution of radionuclides in a series of ocean water profiles and surface water stations in the South Pacific Ocean (part of a coordinated programme of research in marine radioactivity studies).

SUPPORTED BY Intl. Atomic Energy Agency - Austria

2.0279, ACCUMULATION OF RADIONUCLIDES BY VERTEBRATES

J.P. BAPTIST, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Beaufort, North Carolina* 28516

Estuaries and brackish water areas provide a nursery ground and habitat for many commercially important fish. They also provide receiving waters for waste products, including radioactive effluents from power reactors, hospitals, and laboratories. Marine vertebrates can concentrate radioactive elements which could be harmful to them and render them useless as seafood for man. Since the marine environment is complex and each estuary is different, in some way, from all the others, various factors influencing accumulation must be studied under laboratory conditions.

The objectives of this project are to measure under controlled laboratory conditions, the accumulation and retention of radionuclides by marine fish, to study the importance of various factors which may affect accumulation, and to observe the feeding processes of commercially important fish through the use of radioactive tracer techniques.

Experiments are conducted with several marine fishes such as croakers, Micropogon undulatus, mummichog, Fundulus heteroclitus, pinfish, Lagodon rhomboides, bluefish, Pomatomus saltatrix; and flounder, Paralichthys sp. Accumulation of radionuclides both from sea water and from natural food containing radioactivity in known concentrations is determined.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish

2.0280, ACCUMULATION OF RADIOACTIVITY BY INVERTEBRATES

T.J. PRICE, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Beaufort, North Carolina* 28516

The rapid growth of atomic energy industries and the increased use of nuclear reactors for power production have increased the possibility of the contamination of the marine environment with radioactive materials. Also, radioisotopes used in research and medicine may be disposed of in coastal waters, which are habitats for many species of commercial marine invertebrates.

Since many invertebrates are filter-feeders, omnivorous predators, and scavengers, it is probable that these animals come in contact with most components of the ecosystem. If one or more of these components contain radionuclides, it is probable that this radioactivity eventually would become associated with these animals.

Laboratory research is being done to determine the uptake, accumulation, and retention of specific radioisotopes (zinc-65, iron-59, iodine-131 and others) by marine invertebrates, including clams, oysters, scallops, and crabs. From these experiments, one can ascertain the importance of various factors which may affect accumulation; observe the metabolism of specific elements by invertebrates through the use of radioactive tracers, and study the foods and feeding activities of marine invertebrates.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish

2.0281, THE ACCUMULATION OF FISSION PRODUCTS BY MARINE FISH AND SHELLFISH

T.R. RICE, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Beaufort, North Carolina* 28516 (AT(49-7)-5)

Objective: The cycling of elements in the estuarine environment is being followed by observing the movement of radioisotopes in the water, biota, and sediment phases of the estuary. Quantitative data on the cycling of radioactive elements are being taken. With such data, it should be possible to predict the pathways taken by the radioactive elements.

The potential importance of cord grass, Spartina alterniflora, in conveying radioisotopes of zinc, manganese, and iron into estuarine food chains was evaluated. An environmental tracer experiment was carried out in which naturally-occurring fallout radioactivity in the estuary served as the tracer isotopes. In the laboratory the influence of certain environmental factors on the concentrations of zinc accumulated by an experimental community was tested. Finally, the interactions of radiation, salinity, and temperature on the physiology of the estuarine fish, the mummichog, was observed.

Results: Spartina production was found to approach one-third the total phytoplankton net production of adjacent estuaries and is thus potentially important in estuarine food chains. The unusually high iron content (5,000 ppm. dry wt.) of the dead material suggested that Spartina may be especially important in the movement of radioisotopes of iron from water and sediment into estuarine animal populations. Concentrations of gamma-emitting fallout radioisotopes were monitored in Rangia over a 30-mile stretch of river and a salinity range of less than 0.1 to greater than 15 ppt. Ruthenium 106 and ruthenium 103 were concentrated more in Rangia from downstream stations (salinity range 6- 15 ppt), whereas cesium 137 was more abundant in the same species from fresher water (salinity range 0-8 ppt). It was found that a high salinity and zinc concentration suppressed the concentration of zinc 65 in animals and sediment, while high temperature and pH had the opposite effect. In experiments testing the interaction of salinity, temperature, and radiation, it was observed that both salinity and temperature changed the LD-50. Above 20 degrees C. fish were more sensitive to radiation at high salinities, while below 20 degrees C. fish were more sensitive to radiation at low salinities.

SUPPORTED BY U.S. Atomic Energy Commission

2.0282, PRODUCTIVITY OF ESTUARINE AND MARINE ECOSYSTEMS (A COOPERATIVE AGREEMENT WITH THE ATOMIC ENERGY COMMISSION)

R.B. WILLIAMS, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Beaufort, North Carolina* 28516

All life ultimately depends on autotrophic organisms. Therefore, knowledge of primary production in estuaries is required for evaluation of their potential to produce commercially important fish and shellfish and for elucidation of the movement of radionuclides through estuarine food chains into edible species. The primary production of phytoplankton and benthic algae, two groups of autotrophs important in the characteristically shallow southeastern estuaries, is being measured at regular intervals in inshore waters near Beaufort, North Carolina. Phytoplankton production is estimated by the light and dark bottle technique. Bottles of seawater (with zooplankton removed by filtration) are incubated for 24 hours at several fractions of surface illumination, and changes in dissolved oxygen are determined by titration. To estimate benthic production, areas of bottom are enclosed (in situ) for 24 hours beneath clear and opaque plastic bell jars, and changes in dissolved oxygen within the jars are obtained by titration of water samples withdrawn from them. In addition, measurements of standing crop accompany the measurements of production.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish

2.0283, CYCLING OF TRACE METALS IN THE ESTUARINE ENVIRONMENT

D.A. WOLFE, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Beaufort, North Carolina* 28516 (AT(49-7)-5)

Information on the cycling of trace metals in an estuarine ecosystem is necessary to establish which components of the biotic and abiotic systems serve as reservoirs for these elements. The application of the specific activity concept, which can be used to establish the maximum permissible concentration of certain radionuclides in the aquatic environment, requires a knowledge of the distribution and concentration patterns of stable elements. We have chosen manganese, iron, and zinc for our studies because each of these have neutron- induced radionuclides which are accumulated to relatively high levels by aquatic biota and are present in atmospheric fallout and in discharge waters of nuclear power plants and ships. This research consists of both field and laboratory studies. Our field studies are

conducted in the Newport River estuary and consist of describing the concentrations of manganese, iron, and zinc in estuarine sediment, water, and biota and constructing a budget of the movement of these elements through the estuary as a result of physical and biological processes. Laboratory research deals with the dynamics of exchange of these elements among sediment, water, and biota, so that, ulimately, we will have the information required for the development of prediction equations for the distribution of contaminant radionuclides in the estuarine ecosystem.

Results: Concentrations of manganese, iron, and zinc in sediment and water samples collected from the Newport River estuary decrease in a seaward direction and have considerable temporal variations. Concentrations of these elements in estuarine fish varied with both body size and species. A comparison of physical and biological transport of manganese, iron, and zinc in the Newport River estuary showed that biological export of manganese and iron was less than 0.1 percent of the total import of these elements from river flow. Biological export of zinc, however, was estimated to be about 10 percent of total import.

Part 1 of 3.

SUPPORTED BY U.S. Atomic Energy Commission

2.0284, SEDIMENT MINERALOGY
D.A. WOLFE, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Beaufort, North Carolina* 28516

Sediments have the capacity to scavenge many radionuclides from sea water. There is, however, little agreement as to the effect of this phenomenon on the food web of the sea. Will this scavenging action enhance or reduce the uptake of radioactivity by the biota? If organisms have the capacity to utilize the organic matter in sediments as a source of nourishment, sediment-sorbed activity could be passed along the food web to eventually reach man. Conversely, by adsorbing radioactive materials from sea water, sediments could reduce the possibility of contamination in many pelagic animals.

In order to determine the role of sediments in the cycling of radionuclides in the estuarine environment and to gain some insight into sediment-animal relationships, experiments on sediment-sorption of radionuclides are being carried out in the laboratory and in the field. Observations are made on the capacity of natural sediments and selected clay minerals such as montmorillonite, to scavenge radionuclides (zinc-65, cesium-137, and chromium-51) from sea water of varying salinity. Also, the partition of these radionuclides between the sediments, and biota of outdoor ponds will be studied.

2.0285, FATE OF POLLUTANTS IN ESTUARIES AND MARINE BAYS
C.R. OMELIA, Univ. of North Carolina, School of Engineering, *Chapel Hill, North Carolina* 27514

This project will investigate and establish a means for predicting the distribution and effects of particulate and colloidal pollutants in coastal waters.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0286, ENVIRONMENTAL INVENTORY, AQUATIC AND TERRESTRIAL, BELEWS CREEK-BELEWS LAKE, N.C.
C.M. WEISS, Univ. of North Carolina, School of Public Health, *Chapel Hill, North Carolina* 27514

The environmental impact of a 2.8 megawatt fossil fuel steam power plant on the aquatic environment and surrounding terrestrial environ of a 3000 acre cooling water pond is under study. As the lake is filling and the power plant is under construction detailed baseline studies of the aquatic biota and water chemistry of both the inflowing streams and lake are in progress. Particular attention is being made to nutrient levels in the aquatic environment as well as population characterisitics of the aquatic biota. Detailed botanical transects will be made on shore line areas to establish baselines for long term trends. Aereal mapping of the region is scheduled each year with photographs being made in black and white, true color and reversed color.

SUPPORTED BY Duke Power Company - Charlotte, N.C.

2.0287, WATER QUALITY MANAGEMENT OF IMPOUNDMENTS
C.M. WEISS, Univ. of North Carolina, School of Public Health, *Chapel Hill, North Carolina* 27514

The proposed investigation will establish potential levels of eutrophication in New Hope Lake following completion of New Hope Dam. This will be accomplished by a systematic water quality sampling in the Haw and New Hope rivers which will fill the basin behind the dam. Both rivers now carry a considerable pollution load. Since the proposed lake will undergo thermal stratification, during summer months, with rapid deoxygenation of deep levels, pilot studies will be carried out on University Lake, the near-by water supply reservoir of Chapel Hill, on which ten years of limnological data have been accumulated, to ascertain methods and procedures for destratification by air-lift or mechanical pumping. The information gathered on University Lake will be extrapolated to New Hope. In Phase II, a second three-year period, a suitably scaled-up installation will attempt to improve water quality by destratification of New Hope Lake.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0288, QUALITY OF STORM WATER DRAINAGE FROM URBAN LAND AREAS IN NORTH CAROLINA
E.H. BRYAN, Duke University, School of Engineering, *Durham, North Carolina* 27706

The objective of the proposed research is to determine the relationships between land use and the quality of storm water drainage in an urban area of North Carolina. The drainage basin selected for study will typify the pattern of land use in an urban and urbanizing setting in North Carolina. Quality of storm water from commercial, residential, industrial, public and institutional sub-basins with respect to selected parameters such as alkalinity, pH, chlorides, solids, nitrates, phosphates, pesticides, herbicides, coliforms, biochemical oxygen demand, organic carbon and others will be related to existing and changing patterns of land use. The project will be aimed at furnishing a background of information as to sources and amounts of pollutional substances contributed in a diffuse pattern to natural drainage channels.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0289, ANALYZE PRECIPITATION SAMPLES FOR SELECTED COMPONENTS
UNKNOWN, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: To determine selected pollutants in precipitation samples.

Approach: To determine those pollutants which are wash-out or incorporated as rain-out, particularly the pollutants which are of interest to NAPCA.

Goal: To determine pH and other pollutants in precipitation in samples collected biweekly at 16 stations.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

2.0290, SOURCE, FATE AND EFFECT OF NUTRIENTS ADDED TO NORTH CAROLINA ESTUARIES
B.J. COPELAND, Univ. of North Carolina, School of Liberal Arts, *Raleigh, North Carolina* 27607

To study the effects of sewage and industrial wastes on the water quality of North Carolina's sounds and estuaries.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0291, NUTRIENTS AND EUTROPHICATION IN A NORTH CAROLINA ESTUARY
J.E. HOBBIE, Univ. of North Carolina, Graduate School, *Raleigh, North Carolina* 27607

A continuation of Project B-004-NC relative to the Pamlico estuary of North Carolina with the following specific objectives: 1. To measure the annual cycle of concentrations of nitrogen compounds (nitrate, nitrite, ammonia, dissolved organic

nitrogen) throughout the estuary as well as some physical and chemical factors that might be influencing these concentrations (e.g., stratification, anaerobic layers). 2. To measure the sources and quantities of phosphorus and nitrogen entering the estuary from the Tar River and other smaller tributaries. 3. To investigate in detail nutrient factors limiting phytoplankton photosynthesis throughout the year and in different parts of the estuary. 4. To follow the spring algal bloom in detail in order to determine, if possible, if this bloom is correlated with recent eutrophication or is a natural phenomenon.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0292, PHOSPHATE MINING EFFLUENT IN ESTUARINE ECOLOGY
D.B. HORTON, Univ. of North Carolina, Graduate School, *Raleigh, North Carolina* 27607

As part of a broader program in estuarine ecology we propose here specific experimental studies of the effluent from phosphate mining operations and its effect on selected component species of the biota. Experiments will be on a scale bridging the gap between observational studies on the estuary as a whole and laboratory studies. At our Estuarine Laboratory a series of pools, and artificial estuaries, will be subject to experimental control, but still much more nearly natural than in the laboratory. This experimental facility will use the phosphate mining operations and the effluent settling basins through experiments described here, with measurements of four principal biological parameters; the bottom fauna; the periphyton, the plankton, and the rooted plants. Immediate experimental questions include: 1. What is the biological activity of untreated effluent of the mining operations as measurable upon these selected components of the biota? This integrates with our present investigations of chemical and physical characteristics. 2. What is the effect on biological activity, of suspended clays (principally Montmorillonite)? 3. Why does settling reduce biological activity of the effluent? 4. What is the effect of differing substrates upon biological activity of the effluent? Present investigations suggest that most primary production takes place on the bottom where we may expect the nature of the substrate to govern the effect of chemicals added to the system. 5. What is the biological effect of effluent from a sewage treatment plant on estuarine ecology, both alone and in combination with effluent from phosphate mining?

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0293, ROLE OF ANIMAL WASTES IN AGRICULTURAL LAND RUNOFF
D.H. HOWELLS, Univ. of North Carolina, School of Agriculture, *Raleigh, North Carolina* 27607

The principal project objectives are to (1) investigate the pollutional aspects of agricultural land runoff from confined and unconfined animals growing in well defined small watersheds (2) develop relationships between water quality and environmental factors such as animal pollution and hydrology for application to other areas with similar conditions.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0294, WATER CONTAMINATION BY FERTILIZER NITROGEN AND PHOSPHORUS
J.F. LUTZ, Univ. of North Carolina, School of Agriculture, *Raleigh, North Carolina* 27607

The objectives of this project are to determine the direct contribution of fertilizers to nitrogen and phosphorus contamination of surface and subsurface runoff, as affected by: (a) Form of fertilizer applied; (b) Time of application; (c) Rate of application; (d) Crop to which applied; (e) Soil physical and chemical properties; and (f) Meteorological and hydrological conditions. At different times during the period of study, different forms and rates of nitrogen and phosphorus fertilizers will be applied to two completely enclosed watersheds, and to surface runoff plots superimposed on them. Surface losses of nitrogen and phosphorus will be determined by analyzing the soil and water caught in the tanks at the bottom of the runoff plots. Total losses from the watershed will be determined by analyzing the water that passes over the weir at the bottom of the watershed. Soil and plant samples from the watersheds, and water from water wells on the watersheds, will be analyzed.

The two watersheds are on the branch Experiment Station of the North Carolina Agricultural Experiment Station at Waynesville, North Carolina. All analyses will be made in the Analytical Service Laboratory of the Soil Science Department, North Carolina State University, Raleigh, North Carolina.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0295, SOIL PHYSICAL PROPERTIES AND SOIL WATER MOVEMENT
J.F. LUTZ, Univ. of North Carolina, Agricultural Experiment Sta., *Raleigh, North Carolina* 27600 (NC03043)

OBJECTIVE: Determine draw-down patterns of water table by use of electric analogue. Attempt to measure hydraulic conductivity of undisturbed soil cores and relate it to soil properties. Study nature and magnitude of forces holding water films on clays and relate these to hydraulic conductivity.

APPROACH: Further work will be done on the effects of phosphate on the colloidal-physical-chemical properties of clays especially on the hydration of the clay studies will be made on a number of North Carolina soils with emphasis on field capacity and wilting percentage determination. Soil moisture and bulk density determinations will be made on soils under a number of different cultural management and tillage practices to determine the effects of these different practices upon the properties mentioned.

PROGRESS: A. Studies were made on the residual effects of heavy applications of P on the physical properties of soils. Unfortunately the original check plots (1956-64) were fertilized in 1965 and in 1966, so there is no longer a true check plot. The heavily-phosphated plots still have about the same good physical properties as during the 1956-64 period. Fertilizing the original check plots improved their physical properties, thus eliminating differences between the 'check' and the high-P plots. The high-P plots had high total, and available, water- holding capacities, with the greatest increase being in the loosely held water that would be more readily available. The increase in water- holding capacity is caused by an increase in charge of the clay particles, as shown by work with pure clay minerals. Modulus of rupture of packed briquets was correlated with the ratio exchangeable-Ca/exchangeable-Al. B. Soil physical properties that affect water- holding capacity and water movement in soils have been determined on many of the major soil series in the State. The determinations include total porosity, pore-size distribution, bulk density, and a soil moisture characteristic curve from 0 to 15 bars. This information will be useful in soil management, particularly with respect to irrigation, drainage, and leaching of fertilizers, herbicides, etc. Leaching of the chemicals is important because the losses reduce their effectiveness, and may cause contamination of groundwater. This information will serve as a basis for work currently being done on herbicide and fertilizer losses from soils.

2.0296, NUTRIENT EXCHANGES AND SOURCES OF NITROGEN AND PHOSPHORUS IN THE UPPER SHEYENNE RIVER WATERSHED
F.G. DUERR, State Game & Fish Department, *Bismarck, North Dakota* 58501

Objective: To determine the sources nutrient material entering Lake Ashtabula from the Upper Sheyenne Watershed.

Procedure: Obtain flow data and volumetric exchanges of reservoir waters. Take weekly water samples from Sheyenne Watershed from pre- selected sampling stations. Analyze samples of nitrates and nitrites, total nitrogen, inorganic phosphorus and total phosphorus and miscellaneous inorganic ion. Part 2 of 3.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.0297, INFLUENCE OF WATER QUALITY IN MAINTAINING WHITENESS WHEN LAUNDERING WHITE FABRICS

C.M. JANECEK, North Dakota State University, Graduate School, *Fargo, North Dakota* 58102

Objectives: (1) To identify the factors that influence the discoloration of white fabrics when laundered in hard water and/or waters containing iron, manganese or organic coloring. (2) To determine methods that prevent discoloration of white fabrics during laundering. (3) To determine whether any of the methods used to retain whiteness cause a decrease in residual strength or cause other undesirable effects.

It is planned to work with State Extension personnel in enlisting cooperating homemakers. Swatches of white test fabric will be given to each cooperator to be laundered a specified number of times. The swatches will be returned to the laboratory for determination of the degree of discoloration. Information on water supply, iron removal and softening equipment, washing agents and methods will be obtained from each cooperator.

After the factors causing discoloration have been identified, various methods for preventing discoloration will be evaluated. These methods include removal of iron, water softening and the use of selected types of bleach and detergent. Laboratory analyses of the swatches will determine whether or not methods used to attain whiteness are detrimental to the fabric.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0298, NUTRIENT DYNAMICS IN AN ARTIFICIALLY ENRICHED LAKE

J.K. NEEL, Univ. of North Dakota, Graduate School, *Grand Forks, North Dakota* 58201

The primary objective is determination of the effects of weed harvesting upon nutrient level and utilization in a waste enriched lake. The general approach is acquisition of a limnological baseline prior to weed removal and then determination of changes attributable to biomass removal and reduced weed populations. Pre- and post-harvest evaluations will rest upon variation in physical and chemical lake characteristics and weed and phytoplankton populations, primary production by planktonic and attached vegetation, nutrient interactions among water, organisms, and sediments, inflow and outflow of nutrients via surface streams, and overall controls exercised by basic lake and weather conditions. These data should also indicate fundamental consequences of long term enrichment, particularly as affecting lake succession, conditions favoring ascendancy of weeds and phytoplankton, and potential of intra- lake cycling of waste nutrient residues.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0299, THE IMPORTANCE OF THE FOOD CHAIN IN BOTULISM INTOXICATION AMONG WATERFOWL LAKES AND SLOUGHS OF THE DEVILS LAKE REGION IN NORTH DAKOTA

J.R. REILLY, Univ. of North Dakota, Graduate School, *Grand Forks, North Dakota* 58201

This information is designed to investigate the importance of the food chain in the initiation and continuance of epornitics of botulism intoxication among waterfowl and to evaluate possible control methods.

Investigations will involve the following: 1. Examination of natural outbreaks of botulism to determine the type involved, the sources of intoxication and the mechanism of transmission, via the food chain. 2. Determination of the mode of entrance of the organism and its toxin into the food chain. 3. The role of invertebrates in the intraspecific transfer to vertebrates. 4. The possible use of marsh inoculation with B. licheniformis as a control measure to reduce or eliminate botulism epornitics.

2.0300, THE ECOLOGIC IMPACT OF THE INTERACTIONS AMONG MICRO-ORGANISMS AND AQUATIC CONTAMINANTS IN LAKE ERIE

R.M. PFISTER, Ohio State University, Graduate School, *Columbus, Ohio* 43210

Particulate matter in Lake Erie has been examined on a physical, chemical and biological base and characterized using density gradient centrifugation, and electron microscopy. Microbial portions of the Lake Erie ecosystem are also being characterized on the basis of physiological types. Data from these experiments will be correlated in an attempt to establish cause and effect relationships.

SUPPORTED BY Ohio State University

2.0301, ROLE OF FUNGI & ALGAE IN FORMATION AND HYDROLYSIS OF LAKE ERIE SEDIMENTS

V. SANGER, Ohio State University, School of Biological Sciences, *Columbus, Ohio* 43212

The proposed research involves determining the functional role of algal and fungal cells on both formation of and decomposition of the bottom sediments of Lake Erie. The primary approach in this scheme is to elaborate extracellular polymers synthesized by bloom-forming species of blue-green algae and determine its relation to sedimentation. Also, to critically examine the hydrolytic activities of the fungi on Lake's sediments once they have formed. This project will be carried out along the following lines: 1. Species of 'Nostoc', 'Microcystis' and 'Anaebaena' will be examined under laboratory conditions with regard to elaboration of the polymers, and for the polymer interraction with lake particulates and sedimentation. 2. To isolate and grow aquatic fungi in pure culture to study their hydrolytic activities on the bottom sediments (microparticulates) of Lake, taking several parameters into consideration.

Laboratory results would be tremendously helpful in a definite understanding in the biological role of algae and fungi with reference to bottom sediments of Lake Erie.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0302, CHEMICAL AND SEDIMENT MOVEMENT FROM AGRICULTURAL LAND INTO LAKE ERIE

G.O. SCHWAB, Ohio State University, School of Agriculture, *Columbus, Ohio* 43210

Both field and laboratory studies will be involved in measuring the quantity and kinds of soluble and suspended constituents in drainage water from agricultural lands. Precipitation, runoff, soil and air temperature, solar radiation, and other hydrologic factors will be recorded. About eleven common soil chemicals, including nitrogen and phosphorus, and pH, electrical conductivity, atrazine herbicide, and aldrin insecticide in the runoff and in the sediment will be evaluated. In the field studies near Sandusky, Ohio, water samples will be obtained from tile and surface drains installed in one-half acre plots. The land will be cropped in corn with no tillage and conventional tillage practices as variables.

In the laboratory leaching of phosphorus from columns of soil from the field plots will be conducted using various applications of phosphorous. Runoff from small bins containing a fine- and a coarse- textured soil will be analyzed for phosphorous and other ions. The objective of the leaching studies is to identify discrete compounds formed and to determine threshold concentrations where soil contributes phosphorous to lake water.

Water samples taken during the 1969 growing season were high in sediment, and nitrates, but low in phosphorous and dicamba. Atrazine and dicamba losses averaged about 13 percent and 32 percent, respectively, of the amount applied. Water from tile was generally much lower in pollutants than surface water.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0303, A PILOT-SCALE STUDY OF ACID MINE DRAINAGE

E.E. SMITH, Ohio State University, School of Engineering, *Columbus, Ohio* 43212

2. WATER QUALITY

The project activities are designed to establish a systems research approach to the investigation of acid mine drainage. The study will attempt to define the controlling factors and to assess the significance of acidic conditions in abandoned mines, currently inactive ones, and in future mining areas. Attempts will be made to assess the characteristics of acid formation, to establish systems to monitor adequately the variables selected, and to attack the problem with suitable abatement measures.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0304, STRIP-MINING AND WATER QUALITY
J.P. VIMMERSTEDT, Ohio State University, School of Agriculture, *Columbus, Ohio* 43210

Since 1965 when strip mining began on Little Mill Creek Water Shed, weekly samples of storm water have been taken at four sampling points. Two of the points are receiving effluent from the strip mining operation and two are not. The water samples have been analyzed for concentration of manganese, iron, aluminum, sulfate, calcium, and magnesium. These chemical analyses have shown large differences in composition between those sampling points receiving strip mine drainage and those unaffected by these mining operations. Manganese and sulfate concentrations have shown the largest increases.

A sprinkling infiltrometer has been constructed and is being used to measure rate of rainfall in filtration on spoil banks of varied composition.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0305, ENVIRONMENTAL EVALUATION OF A NUCLEAR POWER PLANT
L.S. PUTNAM, State Dept. of Nat. Resources, *Columbus, Ohio* 43212

This study is designed to evaluate the changes in the fish, benthic, and planktonic populations caused by heated-water discharges from a nuclear electric plant.

Collections have been coordinated with the Environmental Protection Agency and the Ohio Geological Survey Study on lake currents. Data collected from June 1, 1969 - May 31, 1971 is in the process of being statistically analyzed and interpreted. Relative abundance and species composition of the fish populations will be estimated. Changes in the populations on a monthly and seasonal basis will be analyzed.

Feeding habits of the fishes as determined by stomach content will be correlated with benthic and planktonic populations near the plant discharge site. Benthic populations will be correlated with substrates.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0306, ENVIRONMENTAL EVALUATION OF A NUCLEAR POWER PLANT
L.S. PUTNAM, State Dept. of Nat. Resources, *Columbus, Ohio* 43212

This study is designed to determine the response of fish and other aquatic animals to heated discharges and relate laboratory estimates to actual changes occurring near a large nuclear powered electrical plant. Temperature preferences of all fishes in the discharge area will be estimated on a seasonal and size class basis. Predictions based on laboratory estimates will be checked during plant discharge.

The effects of sudden temperature shocks within the range of the heated discharge will be studied to estimate the destructive effect of the hot water plume. Standard bioassay tests will be conducted for animals that die as a result of temperature shocks. A wet laboratory at F.T. Stone biology station will be used to test the animals. Handling and adaptation times should be minimized because of the close proximity of the laboratory to the discharge site.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0307, RELATION OF AGRICULTURAL PRACTICES TO WATER QUALITY IN NORTH APPALACHIAN REGION
L.L. HARROLD, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Coshocton, Ohio* 43812 (SWC-027-CCOS-2)

OBJECTIVE: Determine the transport rate of sediment, nitrogen, phosphorus, and selected chlorinated insecticides from agricultural lands into surface and subsurface waters and the transport mechanism thereof.

APPROACH: Develop techniques and equipment for sampling soils, crops, surface runoff, and groundwater recharge and discharge on agricultural watersheds having surface application of selected insecticides and plant nutrients. Relate concentration of pollutants in samples to flow rates. Quantify for various periods total pollutant delivery to surface and subsurface water and relate same to rainfall, soil moisture, soil, geology, and land treatment.

PROGRESS: Great care must be exercised in collecting, preparing, and storing runoff samples to be used in studying the loss of pesticides and other chemicals from agricultural lands. Several individual samples must be collected at variable predetermined time intervals throughout the runoff hydrograph of each storm. Each sample must be related to runoff rate at the time of sampling. A detailed description of the construction and operation of automatic sampling equipment installed on experimental watersheds at Coshocton, Ohio, has been prepared. The equipment remains on a standby basis until the onset of runoff. A predetermined sampling sequence collects samples in 1-gallon glass jugs, which are stored in a refrigerator. Sampling is automatically terminated. Greenhouse and field experiments were conducted in which corn was grown on Muskingum silt loam to which dieldrin had been added. The plants grown in the greenhouse were protected from aerial contamination, whereas no attempt was made to control this in the field. The corn was harvested at maturity and the dieldrin contents of the leaves, stalks, kernels, and cobs were determined. Only slight differences were found between the two experiments in the dieldrin contents of the stalks, kernels, and cobs. But the leaf to stalk ration of dieldrin concentrations in the field-grown plants was 50 times higher than that found in the protected plants. This large difference is attributed to aerial contamination of the foliage.

SUPPORTED BY U.S. Dept. of Agriculture.

2.0308, SPOILS WEATHERING - WATER, SOILS GROWTH
J.P. VIMMERSTEDT, Ohio Agric. Res. & Dev. Center, *Wooster, Ohio* 44691 (OHOO0382-S)

OBJECTIVE: Study the physical and chemical properties of weathering coal spoils: composition of leaching ground water as it changes with time, rain fall distribution between runoff and infiltration, composition of spoil air, variation in spoil temperature with season, depth, and aging, rate of settling of fresh spoil material and change in particle size with spoil weathering determine the spoil factors affecting tree seedling survival growth, and mineral composition.

APPROACH: Continue lysimeter studies and field measures of rainfall. Analysis for chemical composition of leachates collected from lysimeters during 8 years.

PROGRESS: During 1969, we continued collection and analysis of leachate from a battery of lysimeters containing weathering spoil material. The total soluble salt content of the leachate was less than in previous years. All spoil samples, including those initially toxic, now support some plant growth. In view of this, we plan to dismantle the lysimeters and examine the characteristics of the leached spoil material.

SUPPORTED BY Ohio State Government.

2.0309, STRIP-MINING AND WATER QUALITY
J.P. VIMMERSTEDT, Ohio Agric. Res. & Dev. Center, *Wooster, Ohio* 44691 (OHOSS-145)

OBJECTIVE: Determine changes in chemical composition of water in Little Mill Creek following strip-mining for coal; study relationships between reclamation measures and water quality.

APPROACH: Periodic water samples taken at 4 weirs will be analyzed for chemical composition. Three weirs receive water from mined area while one does not. Comparisons will be made between water from mined and unmined area. A portable rainfall simulator will be used to study runoff and erosion from spoil banks, and infiltration of water into banks.

PROGRESS: Chemical analysis of water samples from Little Mill Creek continued. These analyses show large differences in

chemical composition between samples from mined and unmined parts of the watershed. For example, sulfate concentrations at the sampling point nearest the stripmine average 50 ppm higher than those at points unaffected by mining. Even more striking are the very large fluctuations in sulfate concentrations resulting from mining activity. At times, sulfate levels increase to more than 10 times the average level found in the streams receiving mine effluent. The streams unaffected by mining do not have these violent fluctuations. A sprinkling infiltrometer is yielding information relating infiltration rates on stripmines to spoil and reclamation variables. This information will aid in planning improved reclamation methods.

SUPPORTED BY Ohio State Government

2.0310, THE CHARACTERISTICS AND POLLUTIONAL PROBLEMS OF PETROCHEMICAL WASTES
J.A. HORN, U.S. Dept. of the Interior, Federal Water Quality Admin., *Ada, Oklahoma* 74820

Preparation of a comprehensive report reflecting the status of present knowledge regarding pollutional problems associated with petrochemical wastes discharged to the aquatic environment and the effects of such discharges upon water quality of surface streams and groundwater resources in the United States.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0311, CHEMISTRY OF MINERALIZED WATERS
A.G. COLLINS, U.S. Dept. of the Interior, Bureau of Mines, *Bartlesville, Oklahoma*

This project is oriented toward the development of techniques to permit a better knowledge of the chemistry of mineralized waters. Methods previously developed by this group are used to analyze representative oilfield formation waters for Eh, pH, S ion, thiosulfate ion, SO_4 ion, PO_4 ion, NH_4, Li, Na, K, Rb, Cs, Be, Mg, Ca, Sr, Ba, Mn, Fe2, Fe3, Ni, Cu, Zn, B, Si, As, Se, F, Cl, Br, and I. The data, plus geologic data, and associated petroleum data are correlated and interpreted in reference to origin of the mineralized waters, origin of petroleum, and water pollution. The research has revealed new sources of valuable elements such as iodine and bromine. All the results are published thus establishing mineralized fomation water reference data.

As time permits the solubilities of certain inorganic constituents such as barium sulfate, and strontium sulfate and organic constituents in mineralized waters and determined. These data are very useful in developing better methods to produce petroleum.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

2.0312, GEOCHEMISTRY OF OILFIELD BRINES
A.G. COLLINS, U.S. Dept. of the Interior, Bureau of Mines, *Bartlesville, Oklahoma*

The project is oriented toward the development of knowledge concerning the origin of oilfield brines, how they are related to petroleum and gas, what economically recoverable constituents do they contain, and how to dispose of them so that they will not pollute fresh waters and land. Samples of oilfield brines are obtained from most of the sedimentary basins of the United States and analyzed to determine their chemical and physical characteristics. These data are made available to the National Office of Water Data Coordination so they can be used in pollution control. Additionally, geochemical studies are made with the data through the use of maps and automatic data processing correlation techniques. Significant findings are published to aid federal and non-federal agencies in improving exploration and production techniques, in evaluating brines as sources for valuable and strategic constituents such as iodine, lithium, bromine, etc.

Modern methods of analyzing brines are developed using new types of instrumentation. The project leader is chairman of an American Society for Testing and Materials Section and every effort is made to provide ASTM with acceptable standards for publication, and in addition he works with three task groups to develop acceptable standards for the Federal Advisory Committee on Water Data.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

2.0313, SEDIMENT YIELD IN RELATION TO WATERSHED FEATURES IN THE SOUTHERN PLAINS
P.B. ALLEN, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Chickasha, Oklahoma* 73018 (SWC-014-ECH-3)

OBJECTIVE. Develop procedures for predicting the sources, amount, rate, and character of sediment yield and delivery from agricultural watersheds of varying sizes in the principal physiographic and climatic regions of the area; and determine the effects of upstream watershed protection programs on sedimentation along the main stem of river systems.

APPROACH. Before and after basin treatment collect and analyze sufficient floodwater samples to define continuous suspended sediment transport by size ranges at enough gaging sites to accomplish objectives. Compute unmeasured load with one or more of the applicable methods. Use available flow, land use, cover, and rainfall data to relate variables. Periodically survey reservoir ranges for sediment accumulation; determine inflow with continuous stage record; determine trap-efficiency with occasional outflow water samples.

PROGRESS. Of the land uses being studied it appears that overgrazed rangeland and rangeland in poor condition are the major sediment production areas. Sizable reductions in sediment yield occurred on each of four watersheds when flood retarding reservoirs were installed. The magnitude of the reduction varied from 40 to 60 percent. Due to inherent inaccuracies in the analysis methods and the short period of data, reduction magnitudes must be viewed with some reservation. The fact that general agreement was found by two computational procedures lends some credulence to the findings, however. On Winter Creek some of the yield reduction resulted because channel bank erosion was stopped by the regulated flows through the reservoirs. Although reservoirs greatly reduced yield at the Sugar Creek gaging station, no change could be detected on the Washita River. The sanded-in Sugar Creek channel caused most of the transport to be spilled on to the flood plain before it reached the river. Sediment transport on the Washita River sharply increased when the Sugar Creek channel was dredged.

SUPPORTED BY U.S. Dept. of Agriculture

2.0314, EFFECT OF AGRICULTURAL CHEMICALS ON THE QUALITY OF GROUND AND SURFACE WATERS
R.G. MENZEL, U.S. Dept. of Agriculture, Agriculture Water Mgt. Lab., *Durant, Oklahoma* 74701 (SWC-027-EC-1)

OBJECTIVE. Determine when, under what conditions, and what extent the use of agricultural chemicals is impairing the quality of our water resources; develop practices to minimize the movement of contaminants into ground and surface waters.

APPROACH. Studies will be conducted in laboratories for the development of principles and concepts which will then be tested on field plots or small watersheds. Soil and water samples from treated plots and watersheds will be collected and analyzed to determine loss of chemicals by runoff. Soil profiles of selected areas will be sampled and analyzed to assess the effect of past management practices on the movement of nitrate and other contaminants through soil.

PROGRESS. The three staff members of the U.S. Agricultural Water Quality Management Laboratory occupied the newly completed buildings during the closing weeks of 1969. Therefore, accomplishments during 1969 were mainly in research planning, recruitment, and instrumentation of the Laboratory rather than in technical results. Goals for the Laboratory research program are: (1) a continuing national evalutation of potential agricultural soil and water pollution problems; (2) establishment of reliable sampling and processing methods for field studies on such pollution; and (3) obtaining field data on movement of agricultural chemicals through cooperation with various locations of the Soil and Water Conservation Research Division. Attempts are being made to recruit scientific and support staff within strong personnel and financial limitations. Because of these limitations, most recruitment involves potential transfers of Division personnel. An agricultural engineer and a biochemist will join the staff in June, 1970. Instruments that have been installed and tested include a radiation analyzer, spectrophotometer, atomic absorption flame

photometer, microscopes, and pH meters. Work has started on the design of a moisture flux meter which is to be used in studies on movement of agricultural chemicals in ground water.

SUPPORTED BY U.S. Dept. of Agriculture

2.0315, PLANKTON PRODUCTIVITY OF LAKE ATITLAN, GUATEMALA, IN THE TROPICAL SAVANNA HIGHLAND OF CENTRAL AMERICA
T.C. DORRIS, Okla. St. Univ., Graduate School, *Stillwater, Oklahoma* 74075

This is a study of productivity and structure of the plankton of Lake Atitlan, Guatemala, a large, highland lake in the tropical savanna of Central America. The lake was formed as a result of volcanic activity. Tropical lakes are expected to be very productive because of the potentially large solar influx and the year-round uniformity of temperature. Development of a major hydroelectric project in the near future will bring river flows into the lake to replace the water taken out for generation. It seems likely that the clarity of the lake will be greatly changed, with consequent changes in the biotic populations. The sampling program will be completed about twice each month. Information will be obtained on solar input and penetration, air and water temperature, precipitation, phosphorus, nitrate, silicate, dissolved oxygen and carbon dioxide, pH, alkalinity, plankton pigments, plankton populations, primary productivity and community respiration by in situ and light-dark bottle oxygen measurements.

SUPPORTED BY U.S. National Science Foundation

2.0316, SEPARATION AND IDENTIFICATION OF TOXIC COMPOUNDS IN OIL REFINERY EFFLUENTS
T.C. DORRIS, Okla. St. Univ., Water Resources Research Inst., *Stillwater, Oklahoma* 74075

Toxic organic compounds will be removed from oil refinery effluents by steam distillation, liquid-liquid extraction, and adsorption on activated carbon. Toxicity of these fractions will be evaluated with bioassays. The toxic fractions will be resolved into individual compounds by chromatographic techniques and the resolved compounds identified with a combination gas chromatograph-mass spectrometer and/or infrared spectroscopy. Toxic cations will be quantified by atomic absorption spectrophotometry.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0317, BENTHAL SULFIDE RELEASE IN AQUATIC SYSTEMS
D.A. BELLA, Oregon State University, School of Engineering, *Corvallis, Oregon* 97331

The objectives of the proposed study are: 1. To modify the methods of sample collection and free sulfide analysis developed by the investigators of this proposal so that these methods might be effectively utilized by regulatory agencies, 2. To investigate the extent of significant benthal free sulfide release within a variety of aquatic systems and, 3. To attempt to gain federal funding for a more comprehensive study into the causes, extent and methods of control of benthal free sulfide release. (Objective 3, will only be done if the results of objective 2 indicate that benthal free sulfide release is significant.)

The release of free sulfides from tidal flat deposits into overlying waters has recently been investigated. It was found, under certain conditions, the free sulfide concentration in the overlying waters often exceeded, by significant amounts, levels found to be toxic to many desirable species. Significant free sulfide concentrations were often measured in waters which contained 4-6 mg/L of dissolved oxygen or more. These results indicate that free sulfides released from benthal deposits may often be a more serious water quality problem than the benthal oxygen demand. An extensive literature search has demonstrated that, while benthal oxygen uptake has received a considerable amount of study, benthal sulfide release has been almost totally ignored.

The 'Ten-Year Program' points to the need for detecting and identifying pollutants in water if water quality is to be managed properly. The effect of free sulfides on Oregon's many lakes, streams, reservoirs, and estuaries is not clearly understood.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0318, USE OF REACTOR COOLING WATER FROM NUCLEAR POWER PLANTS FOR IRRIGATION OF AGRICULTURAL CROPS
L.L. BOERSMA, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

The proposed research plan involves laboratory investigations directed at determining the feasibility of using water heated in nuclear power plants for irrigation of agricultural crops. The main approach in the proposed investigations is to determine the influence of soil temperature and heated water on rates of photosynthesis, transpiration and respiration under controlled laboratory conditions.

Methods employed are: A special experimental arrangement has been designed in which soil water content and soil temperature can be maintained constant or can be varied at a programmed rate. Above ground conditions can be maintained constant or can be varied at a programmed rate independent of below ground conditions. The rates of photosynthesis, transpiration and respiration can be monitored on a continuously recording basis or measured at certain time intervals. The experimental arrangements provides for the simultaneous observation of 36 separate plant systems.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0319, REACTOR COOLING WATER FOR AGRO-INDUSTRIAL DEVELOPMENT THROUGH SOIL WARMING
L.L. BOERSMA, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

The proposed research plan involves laboratory and field investigations directed at the determination of the potential use of cooling water from nuclear power generating stations in agriculture. The main objective of the investigations is to measure the temperature and moisture regimes in soils with buried pipes through which warm water is flowing. Results will be analyzed to arrive at design criteria for the construction and operation of an underground pipe network for maximum heat disposal efficiency and optimum plant growth.

Laboratory investigations would employ the following methods: 1. Simultaneous transfer of heat and water would be measured in soil slabs where both heat and water are added to the soil from a point source below the soil surface. 2. Mathematical models would be developed for the predictions of heat and water movement for a range of soil physical and meteorological conditions.

Field investigations would involve experiments designed to verify laboratory results under field conditions and to compare crop growth on plots with different thermal and moisture regimes.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0320, ECOLOGICAL AND RADIOECOLOGICAL STUDIES IN THE COLUMBIA RIVER, THE ESTUARY AND THE ADJACENT PACIFIC OCEAN
N. CUTSHALL, Oregon State University, School of Science, *Corvallis, Oregon* 97331 (AT(45-1))

This project involves studies of radionuclide and trace element cycling in the Columbia River system. The overall objective is to increase understanding of the dynamic partitioning of trace materials between solution, sediment and biota in fresh, brackish and seawaters. This objective is sought in two ways, through direct measurement of radionuclides and trace elements in various phases of the system and through mechanism-route inferences drawn from these direct measurements coordinated with measurement of other ecologic' parameters.

Sorption onto suspensoids and bottom sediments affects availability of trace materials to organisms and transport rates. Sorption mechanism determines the liklihood for subsequent desorption when new conditions are encountered. Flow rates and mixing rates must be known as they affect distribution of trace materials. Living organisms are important not only as a focal point but also as they influence trace materials cycles directly.

Population structure and variability in pelagic and nektonic communities and relationships of these communities to the physical environment are being elucidated.

Important reservoirs for Zn65, Cr51, Co60, Mn54 and Sc46 in the Columbia River system have been identified and some of the transfer routes determined. These radionuclides have been used to estimate rates of ecological processes such as: flow, biological utilization and transport of suspensoids and to estimate food-chain transfer efficiencies for isotopic trace elements.

SUPPORTED BY U.S. Atomic Energy Commission

2.0321, STUDIES ON EFFECTS OF WATERSHED PRACTICES ON STREAMS
J.D. HALL, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331

Objectives of this study are to determine the effects of timber harvest practices on the physical and chemical characteristics of coastal streams and on fixation of energy by stream periphyton and inflow of organic detritus. Mean levels and variabilities of suspended sediment discharge, stream temperature, net solar radiation, chemical water quality, primary production by periphyton, and inflow of plant detritus will be established during a two year pre-logging period 1966 through 68. Studies will continue during logging in 1966 and for two years after harvest.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0322, EFFECT OF WATERSHED PRACTICES IN COASTAL STREAMS
J.D. HALL, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00526)

OBJECTIVE: Determine relationships of land use practices to quantity and quality of water and to biotic resources of coastal streams, determine if land use practices can be modified in order to increase and improve water sources in coastal watersheds.

APPROACH: Cooperate in pilot soil-vegetation survey (resource inventory) of Alsea River watershed led by Soils Department, Oregon State University. Conduct study of the effects of timber harvest upon the physical-chemical and biotic resources of three small coastal streams. Conduct water resource inventory of major Alsea River tributaries, obtaining base data for watershed research.

PROGRESS: Rapid regrowth of vegetation on the slopes and along the stream in the completely clearcut watershed has caused an amelioration of the severe environmental conditions noted after logging in 1966. Stream temperatures have moderated significantly, the maximum temperature noted in 1967 was 85 F, 1968 - 80 F, 1969 - 75 F. Suspended sediment levels were reduced in the 1968-69 winter in comparison with the first two winters following logging. Hydrologic research has indicated that a significant increase in peak flow for a given rainfall intensity accompanied clearcutting of the large watershed, Needle Branch. Lesser effects were noted on the patch-cut units in Deer Creek. A study of changes in the intragravel environment following logging was completed during the year. Dissolved oxygen levels in the gravel water were significantly lower on Needle Branch than in Deer Creek. Fluctuations in the temperature of intragravel water paralleled those of surface water in the completely clearcut stream, but were significantly reduced in magnitude. The resident population of cutthroat trout in the clearcut stream showed a significant increase this year, after three years at about 75% of their prelogging abundance, but the level was still below the unlogged mean. Outmigrant cutthroat, also reduced for two years following logging, have increased in abundance in the last two years to higher than pre-logging levels. The Coho salmon seaward migrants continue to show no significant effects of the clearcut logging.

SUPPORTED BY Oregon State Government

2.0323, SEDIMENT-WATER-BACTERIA INTERACTION IN EUTROPHICATION
R.Y. MORITA, Oregon State University, Graduate School, *Corvallis, Oregon* 97331

Current research is oriented toward towards the basic contributions of microorganisms in the water and sediment to the process of eutrophication--mainly in terms of recycling of matter so that they will be available for the photosynthetic forms. In Upper Klamath Lake, Aphanizomenon flos-aquae is the dominant photosynthetic organism. Unfortunately, we have not been able to obtain a bacterial free culture of this organism. By employing C^{14} compounds, we have been able to determine the rate of microbial activity on amino acids, glucose and glycollic acid; that is the flux status of these compounds. New techniques have been developed to determine the rate of respiration in relation to these compounds as well as their incorporation. We are currently trying to develop new techniques so that we can determine the rate of activity of microorganisms in the sediment.

We have also been able to demonstrate phosphate solubilization by bacterial action as well as by cryptic growth along with the ability of many of the bacteria to hydrolyze RNA and DNA which are the main phosphate organic molecules. Many of the organisms have been shown to produce B12 and most of the bacteria associated with the blue-green algae do produce B12. B12 is never limiting in this lake as it is found in sufficient amounts both in the water and sediment.

This project was started on April 1, 1968 and the grant terminates March 31, 1971. Unfortunately, this study cannot be completed within the three year period of this grant and renewal will be requested when the appropriate time arrives.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0324, SEDIMENT-WATER-BACTERIA INTERACTION IN EUTROPHICATION
R.E. PACHA, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00895)

OBJECTIVE: The major objective is to investigate the microbial activity in lake sediments to determine the effect of this activity on eutrophication. In particular it is of interest to define the importance of bacteria found in bottom muds in the recycling of plant nutrients between sediments and overlying water.

APPROACH: The vertical and horizontal occurrence of various physiological types of bacteria in the bottom sediments of upper Klamath Lake, Oregon will be determined. From the bacteria isolated in the field studies, a few of the organisms will be selected and their activity on the substrates in the sediments investigated. The effect of environmental parameters on the activities of the organisms will also be examined.

PROGRESS: The various physiological types of bacteria present in a natural eutrophic lake (Upper Klamath) have been completed. The vitamin B(12) and phosphate problems have been investigated and it appears that these are not limiting in a natural situation. B(12) is produced by many isolates from the lake as well as those contaminating Aphanizomenon flos-aquae. A bacterial free Aphanizomenon has not been obtained as yet. Cryptic growth of bacteria releases phosphate. Isolates from the lake can dissolve various phosphate minerals to release phosphate. We are looking at the organic flux in the lake also.

SUPPORTED BY Oregon State Government

2.0325, THE AUTECOLOGY OF SOME BLUE-GREEN PLANKTON ALGAE
H.K. PHINNEY, Oregon State University, Graduate School, *Corvallis, Oregon* 97331

Autecological and synecological studies using both uni-algal and mixed cultures of selected species important in nuisance blooms. The study will determine 1) requirement for major and minor nutrient minerals, 2) effects of naturally occurring organic nutrients, and 3) possible biotic effects as antagonism and synergism or competition in mixed cultures.

Analysis of the effects upon growth of the factors under consideration will be by the following determinations: 1. Dry weight. 2. Percent organic matter. 3. Caloric value. 4. Pigment content. 5. Dry solids by interferometry. 6. Direct mineral analysis, and 7. Direct determination of production rates.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0326, SOIL STABILIZATION AND RUNOFF REGULATION IN CONIFER WATERSHEDS OF WESTERN WASHINGTON AND OREGON

J.S. ROTHACHER, Oregon State University, U.S.D.A. Pac. Nw. Forest Sta., *Corvallis, Oregon* 97331 (PNW1602)

OBJECTIVE: To determine how logging methods, road construction, and forest management practices can be improved to curtail erosion, prevent channel impairment, maintain water quality, and regulate quantity and timing of runoff.

APPROACH: The project will study erosion production and mass soil movements resulting from logging and road building; quantity and timing of runoff; and water quality. Various cutting methods will be investigated to determine their comparative effect on streamflow, soil movement, sedimentation, and chemical quality of water. Forest management in the Douglas-fir region will be studied in relation to soil moisture and water yield.

PROGRESS: In the conifer watersheds of western Washington and Oregon vegetation is a key factor that the land manager can control to protect the soil and water resource. Successful land management requires an understanding of the successional and environmental relationships of the various plant communities. Logging and slash burning of mature forests drastically modify the existing vegetation and establish a changed environment for a new succession of plant communities. Fortunately, regrowth is rapid in western Washington and Oregon where vegetation cover was found to reach almost 50 percent by the end of the second growing season. During the first years after logging and burning, elimination of vegetation that previously shaded the stream channel resulted in increased maximum water temperatures during the summer. June, July, and August maximum increases in water temperatures may exceed 12 to 14 F. Vegetation plays an important role in maintaining infiltration of water into the soil mantle. The soil characteristics influence the hydrologic properties of the soil including retention and detention storage of water. Research results from small experimental watersheds in western Oregon showed that the single most important factor causing variation in storage capacity was the stone content of the soils. Transpiring vegetation utilizes the soil water during the dry summers characteristic of the Pacific Northwest. Maximum storage capacity available at the end of the dry season is estimated to range from 30 to 40 percent of the total retention capacity values for the soils studied.

SUPPORTED BY U.S. Dept. of Agriculture

2.0327, INFLUENCE OF LOG RAFTING ON WATER QUALITY

F.D. SCHAUMBURG, Oregon State University, School of Engineering, *Corvallis, Oregon* 97331

Water storage of logs is a common practice in the Pacific Northwest. Pollution problems associated with such storage practices have been the subject of a three year study in the Department of Civil Engineering of Oregon State University.

During the first two years of the project, controlled laboratory experiments and well-defined field studies were undertaken to identify types and quantities of pollutants resulting from individual log segments and small groups of logs.

The remaining year will be used (a) to determine the magnitude of the storage problem in the Pacific Northwest and (b) to evaluate the actual degradation of water quality resulting from storage at three selected sites in the region. The methodology and information generated during the first two years of research will be extrapolated to field situations.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua Adm.

2.0328, IMPAIRMENT OF THE FLAVOR OF FISH BY WATER POLLUTANTS

D.L. SHUMWAY, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

The objectives of the project are 1) to develop appropriate standard methods for the evaluation of the flavor-imparting capacity of freshwater contaminants (organic compounds) and 2) to determine the flavor-imparting capacity and degree of flavor impairment of a substantial number of organic compounds that may be capable of imparting objectionable flavor or odor to the flesh of fish.

The project plan of investigation has two distinct phases. The first phase encompasses a construction period (2 months) and a methodology evaluation period (10 months). During this phase 5 organic compounds (o-cresol, 2,4-dichlorophenol, pyridine, n-butanol, and n- butyl mercaptan) will be used in tests designed to determine threshold concentrations, degree of flavor impairment and the influence of light conditions, pH, oxygen concentration, and temperature on these. Also, the rates of pickup and loss of each of these compounds will be studied. During Phase 2, the standard testing procedure deemed most appropriate in phase 1 will be utilized to determine safe levels (do not impart flavor to fish flesh) for 80-100 organic compounds. The second phase will require two years to complete. Rainbow trout and largemouth bass will be used as test animals.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0329, EVALUATION OF PROPERTIES AND QUALITIES OF OREGON SOIL SERIES

G.H. SIMONSON, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00476)

OBJECTIVE: Provide for Oregon soil series a reliable estimate of: properties, such as field morphology, other significant physical and chemical properties, and mineralogy, and qualities such as crop yield potential, fertilizer response, irrigation and drainage behavior, natural vegetation, slope stability, etc.

APPROACH: Compilation of existing characterization and interpretive data from many scattered sources, and organization of the data into a systematic file. Consultation and assistance in planning and execution of research related to soils to achieve selection of experimental and sample locations typical of important soil series. Determination of properties and qualities of selected benchmark series and publication of reports of these data. Identify and map soils of existing experimental areas and sites. Preparation of the list estimate of the properties and qualities of all Oregon soil series.

PROGRESS: Samples were collected for chemical, physical and mineralogical characterization. The results will be useful in making genetic and use interpretations of the soils and used in survey reports for Washington and south Wasco County. The Washington County sample sites were selected according to geomorphic surface to be used for study of landscape-soil relationships in cooperation with project 568. The following samples were collected: 1. profiles of the Fronhofer, Boardtree, Currant, Era, and Day series from Jefferson and Wasco counties. 2. Profiles of the Laurelwood, Helvetia, Kinton, Aloha and Woodburn series from Washington County. A study of septic tank drain field performance in Benton County was started on the Amity, Woodburn, and Willamette series. Effluent dispersal and water table effects were studied. Permeability tests were run by auger hole and double-tube methods for comparison. A more accurate evaluation of septic tank suitability in these soils is expected. A report was prepared for the soil survey of Section 5 Experiment Station in Harney County.

SUPPORTED BY Oregon State Government

2.0330, PESTICIDE MOBILITY AND DEGRADATION IN SOIL-WATER SYSTEMS

V.V. VOLK, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

The objectives of the project are to identify and characterize the physical-chemical properties of the pesticide-soil-water system which are pertinent to 1) pesticide transport through the soil in infiltrating water, and 2) pesticide desorption from eroded soil into surface waters.

Soils have been collected and characterized. Desorption and adsorption studies have been completed with 2,4-D on several Oregon soils. Picloram adsorption studies on nine Oregon soils as a function of surfactant concentration have been complete.

SUPPORTED BY Oregon State Government

2.0331, RADIONUCLIDE CYCLING IN NATURAL POPULATIONS OF AMPHIBIANS

D.L. WILLIS, Oregon State University, Graduate School, *Corvallis, Oregon* 97331 (AT(45-1))

Objectives: Amphibians are important links in both terrestrial and freshwater food chains. Thus, any concern for radionuclide cycling in terrestrial and freshwater ecosystems must include some consideration of their role. The objective of this study is to determine the patterns of uptake, retention and tissue distribution of ecologically important radionuclides in selected amphibians. This involves both laboratory and field studies, so that the effects of natural environmental factors on the metabolism of these radionuclides may be ascertained. The results of this study should serve to clarify the relative importance of amphibians in the transfer of radionuclide contaminants in freshwater communities.

Procedures: Newts (Taricha granulosa) are field-collected. Uptake of Cr51, Mn54, Fe59 and W181 from both labeled food and skin absorption from water, as well as subsequent retention, will be determined by periodic assays with a whole-body counting system. Biological half-life values and loss rate constants will be computer calculated from these data. Serial sacrifice of labeled animals will be used for tissue distribution determinations of the above nuclides and a beta-emitter, such as tritium.

RESULTS: Long term retention of Zn65 in two new newt species has been traced. In addition, extensive studies of uptake from water and/or food, whole-body retention, and patterns of tissue distribution in the newt (Taricha granulosa) for Mn54, Co60, Zn65, Sr85, Rb86, I131 and Cs134 have been completed. Techniques of solubilizing tissues containing tritium for liquid scintillation assay have been developed.

SUPPORTED BY U.S. Atomic Energy Commission

2.0332, EUTROPHICATION - EFFECT OF FLOW AUGMENTATION

A.F. BARTSCH, U.S. Dept. of the Interior, Federal Water Quality Admin., *Corvallis, Oregon* 97330

The immediate objective is to determine the effect on algal bloom production when a nutrient-rich lake is flushed with nutrient-deficient water. Ultimate objective is to decrease or eliminate algal blooms in Moses Lake, Washington. One of three branches of the lake will be flushed with low-nutrient water while the others remain as controls. After flushing during August and September, 1968, a year of no water diversion will follow to permit determining persistence of improvement. This approach will evaluate flushing as a remedial tool and will indicate the periods of future water diversion needed to permanently prevent bloom formation. Principal parameters to be investigated are as follows: 1. Water current studies at selected sites and depths. 2. Water budget studies at selected sites and depths. 2. Water budget studies to determine extent and efficiency of flushing. 3. Turbidity measurements and suspended solids analysis. 4. Chemical and physical parameters to determine existence and character of thermal stratification and also environment for algae. 5. Qualitative and quantitative determination of algae, including measurements of phytoplankton pigments, biomass, and species diversity. 6. Chemical analyses and oxygen demand studies of bottom muds.

Basic data collection and analyses will be conducted cooperatively by FWPCA and University of Washington personnel. Other cooperators will be the Bureau of Reclamation and a citizens group in the city of Moses Lake, Washington.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0333, EUTROPHICATION - BIOLOGICAL CONTROL USING GRAZERS

A.F. BARTSCH, U.S. Dept. of the Interior, Federal Water Quality Admin., *Corvallis, Oregon* 97330

The objective is to determine if living organisms can be found which will harvest nuisance algae through grazing, or reduce them through disease and parasitism. A literature review will be made to determine the prospects for success and to identify North American or other species as prospective candidates for grazing trials. Promising animals will be evaluated in the laboratory or field as appropriate.

It was the consensus of most scientists attending the recent International Eutrophication Symposium in Madison, Wisconsin that this is a potentially fruitful area of research. It was felt that a biological control measure for algae could be found if sufficient effort were expended. This has not been done to date.

Much of the effort in the F. Y. 1968 will be desk work to learn what has been done by other researchers and to determine who might be interested in doing work with grant research funds. Other activities will include preliminary laboratory evaluation of grazer candidates.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0334, EUROPHICATION - PHYSICAL ECOLOGICAL CONTROL

A.F. BARTSCH, U.S. Dept. of the Interior, Federal Water Quality Admin., *Corvallis, Oregon* 97330

The objective is to determine if algal production can be inhibited by preventing thermal stratification of a lake. Prior destratification experiments have sometimes decreased and other times increased primary production. Because of this seeming paradox, it is necessary to understand this phenomenon and to utilize it if possible, as a means of preventing algal bloom formations. If total algal growth can indeed be retarded by mixing, it is necessary to learn if a lake has to be turned over every year or at lesser or greater intervals to give permanent relief.

Principal areas of investigation will include: 1. Measurements of water movements at selected sites and depths in a lake. 2. Measurements of chemical and physical parameters that are of importance to algal growth. 3. Measurements of algal growth.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0335, MARINE BIOLOGICAL ASSESSMENT OF POLLUTIONAL FATE

D.J. BAUMGARTNER, U.S. Dept. of the Interior, Federal Water Quality Admin., *Corvallis, Oregon* 97330

In almost every pollution situation, a major consideration is the impact of the degraded water quality on the organism. This is especially true where it is suspected that the pollutant will harm aquatic organisms of primary importance to man. Interpretation of bioassay tests is complicated by the fact that there has been very little information obtained to relate the controlled observations in the laboratory experiments to the actual conditions existing in the environment in the absence of pollution. Attempting to overcome some of these difficulties, investigators have begun to consider and apply in situ bioassay procedures.

The difficulties associated with this research are related to selection and maintenance of the test animals, of knowledge of their population dynamics in thh natural unpolluted environment, and determination that the observations obtained under the test conditions are due to a pollutional stress rather than artifacts of the experimentation.

The first step in developing a series of procedures for analysis of problem areas is determining the amount and type of information necessary to describe the natural environmental populations. This developmental work is being tried on Yaguina Bay, Oregon, along two approaches.

Information on fish usually associated with bottom or midwater habitat will be obtained at each of ten sampling stations every two weeks by means of a trawl. Continuous recording of salinities on the surface at six stations convering the trawl areas will also be provided. In addition, weekly profiles of dissolved oxygen, temperature and salinity will be provided. Samples will be obtained for organic carbon analysis or PBI's or other appropriate analyses to detemine possible pollutants. It will be possible to test some of the methods of analysis after collection of data for one year. The second method of observation pertains to collection of crustacea in standardized substrate boxes and on substrate media suspended in the water column. These samples are analyzed after exposure to the environment for five weeks. Sub-samples of the organisms obtained in both methods will be analyzed for maturity, weight distribution, and stomach contents.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0336, EUTROPHICATION - SEDIMENT-WATER INTERCHANGE STUDIES
L.P. SEYB, U.S. Dept. of the Interior, Federal Water Quality Admin., *Corvallis, Oregon* 97330

Objectives are to determine mechanisms, rates and conditions by which algal nutrients in lake sediment interchange with overlying water and to treat lake sediment to prevent interchange. Sediment will be removed from the lake and tested for its nutrient release capacity in the laboratory. While most ion exchange work on soil has been done with cations, techniques for this do not take into consideration the possibility of anion exchange with humic and other materials present in organic soils. Ion exchange capacity of lake sediment with reference to anions containing phosphorus and nitrogen will be examined. Because the amount of humic acids in bottom deposits is a measure of the degree to which organic substances are stabilized in sediment and since dehydrogenase content of sediment is a measure of the extent of biological breakdown of organic substances, both parameters will be measured. Also, we may measure the vitamin B12 content since it has been proposed that this vitamin results from bacterial action in sediment.

Small areas of Klamath Lake which have shown dense algal blooms in past years will be isolated from the main body of the lake and used to determine the influence of sediment-water interchange on algal production and to evaluate procedures intended to prevent or impede interchange.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0337, POWER PRODUCTION
B.A. TICHENOR, U.S. Dept. of the Interior, Federal Water Quality Admin., *Corvallis, Oregon* 97330

The project staff acts as a 'core group' for coordinating the FWPCA's national research effort in the area of thermal pollution resulting from power production. Two activities are presently underway: 1. Development of a mathematical model and associated computer program for the prediction of water temperatures in the Columbia River from Grand Coulee Dam to Bonneville dam. 2. Preparation of a 'state of the arts' document describing the present and future problems, present and proposed solutions, and research needs in the area of thermal pollution from power production, with special emphasis on nuclear power plants.

Future plans include either 'in-house', contract, or grant research in the areas of: 1. Reservoir temperature prediction techniques (including stratification, density currents, release temperatures, design considerations for multiple level outlets, operating schedules for optimum downstream thermal conditions, etc.). 2. Dispersion of heat from power plant heated effluent outfalls, 3. New designs for cooling apparatus for thermal power plants, including improvements in methods such as cooling towers, cascades, sprays, cooling ponds, etc., 4. New operating methods or design changes for thermal power plants to produce cooler effluent, 5. Effect of heat on the biological, microbiological, and chemical quality of water.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0338, EUTROPHICATION - EFFECT OF WEED HARVESTING
A.F. BARTSCH, U.S. Environ. Protection Agcy., Office of Water Programs, *Corvallis, Oregon* 97330

The principal objective is to evaluate aquatic vegetation harvesting as a means of effectively reducing algal nutrient availability. Harvesting and removal of aquatic vegetation is one of the potential control measures in combating eutrophication of bodies of water. It is a means of 'cropping off' part of the excess nutrients. Although weed harvesters have been used in the past, no really scientific investigations have accompanied their use. In cooperation with the Pelican River Watershed District, Minnesota, City of Detroit Lakes, and University of North Dakota the effectiveness of the procedure will be evaluated. Attempt will be made to answer such questions as: 1. What is the amount of nutrients actually removed from a lake by weed harvesting? 2. What happens to the energy flow of nutrients that originally went into the plant growth? 3. What is the pattern of regrowth of the vegetation after harvesting and do other species replace the original ones? 4. Does the phytoplankton population change after the higher aquatic plants are removed?

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0339, THE MOVEMENT OF RADIONUCLIDES IN THE COLUMBIA RIVER ESTUARY
D.W. HUBBELL, U.S. Dept. of the Interior, Geological Survey, *Portland, Oregon* 97208

Certain radionuclides enter the Columbia River from the Hanford installation of the U. S. Atomic Energy Commission. Part of the radionuclides remain in solution in the water, part are sorbed on the fluvial sediment, and part are taken up by the biota. As a result, each medium, by virtue of its motion, affects the distribution of the radionuclides.

Objectives of this project are to define the disposition and movement of radionuclides in the Columbia River estuary; to study the processes that influence the movement of radionuclides, particularly the sedimentation, flow and chemical processes; and to contribute to estuarine technology.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0340, HYDROGEOLOGY AND THE EFFECTS OF ACID COAL-MINE DRAINAGE ON GROUND WATER IN TOMS RUN, CLARION COUNTY, PENNSYLVANIA
G. MERRITT, State Bur. of Sanitary Engin., *Harrisburg, Pennsylvania* 17105

Available upon request. Coal mining and oil- and gas-well drilling have adversely affected ground-water quality. Detailed knowledge is not available as to the changes in chemical quality and the areal extent of these changes.

The ground-water flow system was delimited in a small drainage basin in which there were oil and gas wells and abandoned strip coal mines and deep coal mines. Water samples were collected to determine the chemical quality of the groundwater systems and to determine the effects and extent of pollution.

SUPPORTED BY Pennsylvania State Government

2.0341, SANITARY LANDFILLS IN COAL STRIP MINES
G.H. ENRICH, State Dept. of Health, *Harrisburg, Pennsylvania* 17120

Four operating sanitary landfills in the coal strip mines and one in a similar hydrogeologic setting have been drilled to determine the effect the landfills have on the underlying ground water and nearby surface waters. Wells were drilled through the landfill, immediately adjacent to the landfill in the direction of ground water movement, half way between the landfill and near by stream and a well removed from the landfill for background ground water quality. Samples of water were analyzed to determine the effects of the landfills. Leachate from landfill located above the ground water primarily moved laterally on discharge to the surface, having little or no affect on the ground water. Leachate from landfills located in ground water adversely affected the ground water in the immediate vicinity of the landfill. Sampling of the wells is continuing to determine seasonal and time variations.

SUPPORTED BY Pennsylvania State Government

2.0342, DELAWARE ESTUARY SEDIMENTATION STUDY
D.W. MOODY, U.S. Dept. of the Interior, Geological Survey, *Harrisburg, Pennsylvania* 17104

Sediment transport processes in the Delaware estuary are being studied to determine the rate of shoal development. Measured sediment loads delivered to the Delaware estuary by Coastal Plain streams are much less than the annual estimated volume of estuarine sedimentation. Therefore, other sources of sediment must be identified to balance the sediment budget.

Salinity, sediment concentration, turbulence, and many other parameters are known to affect the rate of sediment flocculation. However, little is known about the quantitative effects of the environment upon sedimentation rates. Through field and laboratory experiments the most significant parameters will be identified; these parameters will then be related to rates of sedimentation measured in the field. Results of this study will be used to estimate changes in the present shoaling pattern due to man-made modifications of water quality and the physical geometry of the estuary.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0343, POLLUTION OF SUBSURFACE WATER BY SANITARY LANDFILL

A.A. FUNGAROLI, Drexel University, School of Engineering, *Philadelphia, Pennsylvania* 19104

This study has as its overall objective the establishment of criteria for choosing landfill sites and the development of computer models for use in landfill design and evaluation. There are three long- range objectives: 1. To provide means for predicting the quantitative movement of contaminants to ground water from present and proposed sanitary landfills. 2. To appraise design methods and remedial procedures for reducing any undesirable contaminant movement to within specified limits. 3. To develop hydrologic criteria for evaluating site suitability for sanitary landfills.

An overall objective of this project is to meet these aims by development of mathematical design models that describe the hydrologic functioning of and the contaminant movement from a sanitary landfill in varied geological environments.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0344, SELECTED URBAN STORM WATER RUNOFF ABSTRACTS

U. SCHOENBACH, Franklin Institute, *Philadelphia, Pennsylvania*

The Contractor will catalog, expand and update 'Storm Water Runoff from Urban Areas' April 1966, by compiling selected abstracts from published and unpublished literature covering the subject of urban runoff, from the meteorologic source, through the collection, control, treatment and/or disposal of runoff, via storm sewers, combined sewers, or surface flow and the attendant pollutional effects on all types of receiving bodies of water. A separate listing of those articles or papers pertaining to the report subject and involving pollutional effects in estuaries will be provided. Abstracting and indexing procedures will follow those of the Water Resources Scientific Information Center (OWRR).

This is a joint venture of the Office of Estuarine Studies and the Storm and Combined Sewer Pollution Control Branch.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0345, ACID MINE DRAINAGE - PILOT PLANT EVALUATION

R.A. BAKER, Carnegie Mellon University, Mellon Institute, *Pittsburgh, Pennsylvania* 15213

This program is a pilot-pant study of the factors involved in acid mine drainage formation with emphasis on the effect of microorganisms. It is proposed to pass water of known properties over typical acid- producing mineral layers under controlled conditions in a pilot plant and to measure the rate and quantity of acid production as a function of aerobic and nonaerobic environments and with and without seeding with specific chemoautotrophic organisms. The central feature of the program is the use of actual mine core samples containing the sulfuritic material and/or associated rock strata. The pilot-plant serves as a model of a mine. Thus, results will be immediately relevant to the mine location(s) being studied. The study will simultaneously provide basic chemical and biological data to elucidate the reaction mechanism. This approach is expected to provide practical answers as well basic information in the shortest elapsed time. Other factors being studied include the effect of varying chemoautotrophic seed; recycle; forced aeration; supplemental carbon dioxide; surface area; and nature of pyrite.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0346, OPTIMAL RECREATIONAL DEVELOPMENT IN URBAN RIVERINE AREAS

H.J. DAY, Carnegie Mellon University, School of Engineering, *Pittsburgh, Pennsylvania* 15213

The development of a mathematical model to predict the optimal mix of investments for riverine recreational development in urban areas is the goal of the proposed work. Man-made and natural phenomena such as upstream reservoirs, municipal and industrial pollution, and both hydrologic and geomorphologic conditions would be included in the model. The design criteria would be cost and recreational use; the use levels would be defined according to different income and age groups. The model would be designed to be useful for a wide range of river basins that may require a comprehensive regional study of water based recreation.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0347, USE OF GEL MATERIAL FOR SEALING DEEP MINE OPENINGS

D.R. MANEVAL, Dravo Corporation, *Pittsburgh, Pennsylvania* 15222

It is proposed to adequately seal the portal and adjacent entries of an abandoned drift mine. Reinforced concrete seals will be placed in the openings to provide the adequate safety measures to insure against structural failure of the proposed seal and the release of a large volume of highly acid water.

The proposed seal will be constructed of a chemical grout of low molecular weight polyphenolic polymer. The grout is produced by mixing two solutions; one containing polymer solids mixed with water, and the other containing a catalyst or reaction initiator of a formaldehyde donor and metal salt. The reaction occurring can be timed by use of additional catalyst, almost instantaneously or over a period of hours. Fly ash, on a dry weight ratio basis of 4.1 to the grout will be injected into the mine entries through boreholes from the surface.

Following the construction of both seals approximately 60 tons of fly ash will be pumped into the mine on the inby side of the proposed grout seal. This will insure against any possible leakage around the seal.

A surveillance program will be initiated before, during and after the sealing, to study the effectiveness of the seals and also to determine any changes in the ground water quantity or quality in the areas over and adjacent to the mine site. It is extremely important to know what effect sealing will have on ground water.

The work will be performed on an abandoned mine in Keystone State Park, Westmoreland County.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0348, SUBSURFACE WATER POLLUTION FROM SANITARY LANDFILLS IN CARBONATE ROCK TERRAIN

G.H. EMRICH, Penn. State University, Graduate School, *University Park, Pennsylvania* 16802

Ground water pollution from land disposal of wastes in carbonate rock terrain is a widley occurring problem through the humid United States. Critical information is still lacking of the physical and chemical parameters to be evaluated at land disposal sites.

Sample collecting equipmment has been installed at a sanitary landfill located in central Pennsylvania. The site has at least 50 feet of sandy loam soil derived from the underlying Gatesburg Dolomite. Ground water occurs at a depth of approximately 235 feet.

Liner was placed in the bottom of the sanitary landfill trench. The linear collects and directs all the leachate from the landfill to one side of the trench, where it is evenly spread through the soil. Seventeen suction lysimeters have been placed in the soil at depths up to 34 feet to monitor and collect samples of the leachate. The landfill and monitoring equipment were emplaced in November of 1967. Water was spread on the top of the landfill in order to quickly generate leachate. First leachate production occurred in January 1968 and has moved down to a depth of 12 feet. Chemical analyses of the leachate indicate high concentration of iron, choride, sulfate and B.O.D.

2. WATER QUALITY

A second landfill placed in 1962 is under study. New sampling facilities were installed in the fall of 1969 to compare leachate generation from an older and newer cell. Poor quality water has been traced to the 30 foot depth within soil below the 1962 cell and leachate has migrated to the 10 foot depth below the 1967 cell. Ground water samples beneath this landfill area also show that poor quality water has penetrated to the water table as well (235 foot depth).

2.0349, WATER QUALITY INVESTIGATIONS ON AGRICULTURAL WATERSHEDS IN THE NORTHEAST

W.R. HEALD, Penn. State University, U.S.D.A. Soil & Wa. Cons. Div., *University Park, Pennsylvania* 16802 (SWC-027-APSU-2)

OBJECTIVE: Study factors affecting accumulation and movement of pollutants in soils and water and its effect on water quality from an agricultural watershed.

APPROACH: The kind, amount, variation, source and fate of soluble mineral constituents in surface runoff waters will be determined. Hydrologic and climatic factors associated with the transport of these constituents will be evaluated. Management practices that lead to altering the concentration of these constituents in water will be investigated.

PROGRESS: The concentration of dissolved solids in rainfall in Pa. is an order of magnitude less than that found in the streams of the watershed and about two orders of magnitude less than the chemicals applied as fertilizers. The concentration of soluble P in the surface drainage system averaged less than 15 ppb. This low concentration is the result of very high adsorption capacity for PO(4) by soils of the watershed. Intensive sampling at the outlet of an agricultural watershed showed that one sample taken anywhere in the stream except very close to the banks, accurately represents the average chemical concentration of the stream at that cross section and at that time. Water quality of the stream is directly affected by the hydrology of the area. The stream chemistry responds quickly to changes within the storm hydrograph. Chemical variations in the watershed outflow are a direct reflection of the physical and chemical processes involved in the transformation of precipitation into direct runoff. Acid mine drainage is reflected in increased concentrations of Fe, Mn, Zn, Cu, Co, and Ni in the stream draining the area. However, periodic flooding of the land bordering the stream does not appear to be detrimental to crop growth. Studies on farm ponds revealed that the 10-ppb-P level, often considered the minimum concentration sufficient to promote algal growth, does not provide a demarcation between the eutrophic and non-eutrophic ponds. There is no discernible relation between the concentrations of Fe, Mn, Zn, and Cu on algal growth.

2.0350, GROUNDWATER QUALITY AND THE HYDROLOGIC BUDGET IN A VALLEY UNDERLAIN BY CARBONATE ROCKS

D. LANGMUIR, Penn. State University, Inst. for Res. on Land & Water, *University Park, Pennsylvania* 16802

To determine sources, magnitude, and timing of groundwater recharge, including pollution, and to show how detailed water quality information can provide insights regarding occurence and behavior of groundwater in a valley underlain by carbonate rocks. To determine if water quality information can be used to estimate rates of groundwater recharge, discharge, and movement. To determine in what ways quality information can be usefully correlated with rock mineralogy and other geohydrolic properties.

SUPPORTED BY Pennsylvania State University

2.0351, REDUCTION IN DAMAGES TO FOREST RESOURCES BY IMPROVEMENT OF STRIP-MINING METHODS AND REHABILITATION MEASURES

G. DAVIS, U.S. Dept. of Agriculture, N.E. Forest & Range Expt. Sta., *Upper Darby, Pennsylvania* 19082

Strip-mining disturbs extensive areas in the Appalachian Mountains and creates problems of runoff and erosion until stabilized and revegetated by proper reclamation measures. Weeping lovegrass provides the best initial cover on extremely acid spoils. Spoil pH may be used to predict manganese toxicity in legumes planted on strip-mined lands. Lime is essential to the establishment of crownvetch on coal breaker refuse.

Chemical pollutants in streamflow increase but suspended sediments decrease six months after mining a watershed. Load bearing strength of coal haul roads can be improved by the addition of asphalt compounds. Spoil slides are more likely to occur in the valleys and on steeper slopes in contour strip-mining.

Additional studies are underway which are aimed at evaluating various spoil treatment on runoff and erosion reduction from strip mined areas. Further research is being carried out in the evaluation of various grasses, shrubs, and tree species in conjunction with site preparation and fertilization. Aerial application of seed and fertilizer is being studied.

The actual studies are being carried out at Berea, Kentucky Princeton, West Virginia; and Kingston, Pennsylvania.

The project was started in 1963 with various studies being initiated and others completed at various times. No completion date has been set for the project as a whole.

SUPPORTED BY U.S. Dept. of Agriculture

2.0352, POTENTIAL BENEFITS OF INTEGRATING A NEW COMMUNITY AND A POWER REACTOR WITH SPECIAL REFERENCE TO THE WATER ECOLOGY

D. HAMMERSCHLAG, Univ. of Rhode Island, Graduate School, *Kingston, Rhode Island* 02881

Much progress has been made during the last decade in reducing the cost of nuclear power generation of electric energy. Coupled with a steady increase in energy requirements large power reactors have been considered and built in many instances.

There is a possibility that such a reactor would be built by Narragansett Electric on land owned by them at Rome Point south of Wickford, Rhode Island. The waste heat, which is a by product in the power generation, would be removed by a coolant--in this case the water of Narragansett Bay. Under this arrangement, no benefit is derived from the heat so discharged. In fact, the 'thermal pollution' might create undesirable effects on the water ecology of the area. On the other hand, the excess energy could become a major positive determinant in a carefully conceived new community.

This study will investigate residential, commercial, industrial and public benefits of such a plan, with proper attention to water ecology if the development of a power reactor is fully integrated with and made the focal point of a new community at that location. Techniques developed in the study would not be restricted to this site.

Since this is a truly interdisciplinary subject, an advisory panel with expertise in oceanography, industrial engineering, resource economics and government has been asked by the applicants and agreed to provide guidance.

2.0353, YIELD OF NUTRIENTS FROM AGRICULTURAL LAND TO WATER SOURCES

J.E. SHEEHAN, Univ. of Rhode Island, Agricultural Experiment Sta., *Kingston, Rhode Island* 02881 (RI00239)

OBJECTIVE: Determine pollution of water sources from heavy fertilization of bridgehampton silt and fine sandy loam soils.

APPROACH: Soil samples for determining nitrogen, phosphate and potash will be taken from six soil levels from 4 to 50 inches every 10 days from May through October on fertilized and non-fertilized land. Water samples from surrounding areas will be collected at similiar times from nearby wells, streams and ponds. Soil and water samples will be chemically analyzed for nitrogen, phosphorus and potash. Data collected will be submitted to statistical analysis.

PROGRESS: Various laboratory and sampling techniques tried and tested for accuracy preliminary to initiation of project. Field data collected from June through October.

SUPPORTED BY U.S. Dept. of Agriculture

2.0354, PLANT PHENOLS AND RELATED ORGANIC COMPOUNDS IN PUBLIC WATER SOURCES, THEIR RELATIONSHIP TO CHLORINATION
Y. SHIMIZU, Univ. of Rhode Island, School of Pharmacy, *Kingston, Rhode Island* 02881

Contamination of water sources with organic materials such as fallen leaves or pollens is a common phenomenon in New England area.

The purpose of this research is to determine the potential hazards which may be caused by chlorination of water containing phenolic and other aromatic compounds eluted from plants and other organic materials. The eluted phenolic compounds, such as tannins and flavonoids are expected to inactivate the active chlorine instantly to form the derivatives of chlorinated phenols with potential acute and accumulative chronic toxicities.

The research will involve (1) model experiments on the chlorination of various plant phenols and other aromatic compounds of plant origins, and evaluation of short and long-term effects of the chlorinated products to mice and other organisms, (2) isolation and microchemical determination of phenolic and other organic materials in water before and after chlorination. This will be carried out spectroscopically and chemically with assistance of reference compounds.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0355, A STUDY OF SUSPECTED LEAD POISONING OF SWANS AND GEESE
M. PERRY, State Div. of Conservation, *Providence, Rhode Island* 02903

Objectives: 1. To determine if lead shot is present in sediments of Easton Pond. 2. To determine the concentration of lead in the liver, tibia, and blood of all swan. 3. To determine if acid-fast intranuclear inclusion bodies are present in kidney tissue of all swan. 4. To study the feeding behavior of swans and geese on and near Easton Pond.

Procedures: 1. Sediment samples will be taken at random throughout Easton Pond in Newport, R. I. and analyzed for lead shot contents. 2. All dead swans and geese will be collected and necropsied. Gizzards will be examined for lead shot. Blood, liver and tibia samples will be taken and lead concentrations in parts per million will be determined by use of an Atomic Absorption Spectrophotometer. Technique to be used will be similar to that described in 'Analytical Methods for Atomic Absorption Spectrophotometry,' Perkin-Elmer, Norwalk, Connecticut. 3. Kidney tissue from all dead swans and geese will be examined to determine if acid-fast intranuclear inclusion bodies are present (Lock, Bagley, Irby 1966. Bull. Wildlife Disease Assoc. 2:127- 131). 4. A comparison of lead concentrations will be made between birds at Easton Pond and resident birds from another part of the state.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0356, RADIONUCLIDE MOVEMENT IN GROUNDWATER
J.W. FENIMORE, U.S. Atomic Energy Commission, Savannah River Plant & Labs., *Aiken, South Carolina* 29801

Large volumes of very low level radioactive wastes are discharged to two groups of earthen seepage basins. We have investigated both the horizontal and vertical distribution of radionuclides in groundwater between the basins and the nearest flowing stream. Flow paths to the creek were defined using tritium in the waste as a tracer. Results from one basin system show that basin water and trace radionuclides are carried to a maximum depth of 50 feet below the water table and then converge toward the seep line 1600 feet from the basins. At the other basin system, seepage is controlled by closeness to the outcrop zone, principal flow paths being to deep seep line re-entrants. Tritium and 90 Sr are both emerging into the stream. No other radionuclides have migrated more than a hundred or so feet from the basins; 137 Cs migration has not been well defined but is definitely very slow in comparison to 90 Sr and Pu has never been detected in groundwater.

SUPPORTED BY U.S. Atomic Energy Commission

2.0357, UNDERSTANDING OF THE INFILTRATION OF RAIN INTO BURIED WASTE
J.W. FENIMORE, U.S. Atomic Energy Commission, Savannah River Plant & Labs., *Aiken, South Carolina* 29801

Solid radioactive waste is buried in the zone of aeration. With a better understanding of water flow in this zone, we can better protect waste from leaching. The waste is buried in trenches excavated to a depth of 20 feet. The frequency and extent of water saturated soil at the undisturbed soil-backfill interface at trench bottoms is being studied. Measurements are being made in 22 wells screened at the interface. Only four of the wells have contained more than a trace of water at a maximum depth of nearly 7 feet.

SUPPORTED BY U.S. Atomic Energy Commission

2.0358, CONCENTRATION OF RADIONUCLIDES BY AQUATIC BIOTA
R.S. HARVEY, U.S. Atomic Energy Commission, Savannah River Plant & Labs., *Aiken, South Carolina* 29801

The objective is to determine the role of plants and animals in the distribution, transfer, and fate of radioactive materials discharged to the freshwater environs of reactor effluent streams.

The ability of these organisms to concentrate radionuclides under optimum growth conditions has been demonstrated. We intend to learn the effects of environmental factors on the radioecology of stream organisms.

Benthic algae were found to be high concentrators of radioactive materials and good qualitative indicators of the radionuclide content of ambient water. Differences in uptake among nine species were more closely related to cell morphology than to generic relationships. Algal radioactivity was influenced by factors such as light intensity, current velocity, and temperature which affect algal growth. Studies with midge larvae, clams, shrimp and fish are in progress.

SUPPORTED BY U.S. Atomic Energy Commission

2.0359, THERMAL INFLUENCES ON FATES OF NUCLIDES
L.J. TILLEY, U.S. Atomic Energy Commission, Savannah River Plant & Labs., *Aiken, South Carolina* 29801 (AT(07-2)-1)

The objective of this program is to be able to predict the fate of radionuclides in lakes and reservoir ecosystems through knowledge gained by studying the distribution, seasonal variation, biological cycling and transport of several radionuclides in a large reactor cooling water reservoir.

This program together with a study of thermal effects forms an integrated program whose objective is a better understanding of structure and function in lake ecosystems in relation to waste heat and radionuclides released by nuclear power plants.

Results to date: Completed detailed determinations of the aerial distribution of total Fe, Mn, Cu, Cr, Sr, (also dissolved Ca, Mg, Na, K, Si, Cl, sulfate, phosphate, nitrate, and organic carbon) in surface water by synoptic surveys (52 stations) during two periods, March and July.

Preliminary work determined the radioisotopes present in the lake and those of ecological importance were selected for further work.

SUPPORTED BY U.S. Atomic Energy Commission

2.0360, GROUND WATER CONTAMINATION RESULTING FROM WASTE DISPOSAL
J.R. ANDERSEN, South Dakota State University, School of Engineering, *Brookings, South Dakota* 57006

Representative waste disposal methods in South Dakota including land disposal of liquid and solid wastes will be investigated to determine: 1. A recommended procedure for selection of waste disposal sites in order to minimize ground water con-

tamination problems. 2. The effects of waste disposal practices including: a. The nature and extent of ground water contamination. b. The effect of ground water contamination on proposed beneficial uses. c. The influence of such factors as climatic conditions, soil types and waste characteristics on the degree and extent of travel of pollutants. 3. A means of combatting undesirable contamination of the ground water.

It is also proposed that the project will investigate the long term effects of solid waste landfill on ground water quality in an area where adequate background data have been collected to observe the initial influence.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0361, POLLUTION POTENTIAL OF RUNOFF FROM LIVESTOCK FEEDING OPERATIONS
J.N. DORNBUSH, South Dakota State University, School of Engineering, *Brookings, South Dakota* 57006

Composited and grab samples of surface runoff from selected production feedlots will be analyzed and the results related to measured precipitation and runoff as well as feedlot characteristics. These data will be related to conditions in the stream receiving feedlot runoff. Analyses of BOD, COD, dissolved and suspended solids, nutrients and coliform organisms will be made.

The objectives of the investigation will be: 1. To determine the quantity and quality of runoff from livestock feeding operations in South Dakota. 2. To relate the above information to hydrological and geological considerations in order to appraise the overall influence of this runoff on specific beneficial uses of receiving waters. 3. To determine the influence of spring feedlot runoff as occurs in northern climates. 4. To determine the pollutional characteristics attributable to the suspended matter in the feedlot runoff in order to extrapolate the effectiveness of proposed lagooning methods of treatment.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0362, QUANTIFICATION OF POLLUTANTS IN AGRICULTURAL RUNOFF
J.N. DORNBUSH, South Dakota State University, School of Engineering, *Brookings, South Dakota* 57006

The project is designed to collect data concerning pollutants carried with agricultural runoff. The objectives of the project are: (1) To quantify the pollutional constituents in agricultural surface runoff; (2) To relate unit pollutant contributions to such factors as soil type, land uses, management practices, and climatological factors; and (3) To relate the portion of pollution constituents associated with both dissolved and suspended solids.

Samples of surface runoff will be collected from representative drainage basins using automatic selfstarting samplers. Spring runoff from frozen land surfaces will receive special attention. Rainfall on and flow from the areas will be measured. Drainage areas will have a variety of crops, and normal farming practices will be followed on the areas. Analyses of samples will include determination of nitrogen and phosphorous forms, pesticides, BOD, COD, dissolved and suspended solids, coliform and other fecal organisms.

Aerial photographs will be used to provide a permanent land use record. The amounts of fertilizer and pesticide applications to the areas will be obtained from the land users and correlated with pollutant contributions in the runoff.

The project was started in February 1970 and is expected to be concluded in January 1973.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0363, ECOLOGICAL FACTORS INFLUENCING THE PRODUCTION OF ALGAE IN NORTHERN PRAIRIE LAKES
L.S. HAERTEL, South Dakota State University, Graduate School, *Brookings, South Dakota* 57006

Four small lakes in eastern South Dakota will be regularly sampled for temperature, chemical characteristics, transparency, phytoplankton, and zooplankton populations. Phytoplankton production experiments will be undertaken. The possibilities of nutrient limitation will be investigated through nutrient enrichment experiments in both field and laboratory. The effect of zooplankton grazing will be examined through experiment and through measures of zooplankton abundance. Fish stomach contents will be analyzed to evaluate potential effects of fish on plankton populations.

The data from laboratory and field investigations will be used to assess the factors controlling the algae populations of the lakes. Whenever possible, correlations will be made involving major individual species as well as the entire algae population.

Project will begin July, 1970 and is expected to be of two years duration, at which time it will be reviewed.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0364, A STUDY TO EVALUATE THE EFFECT OF SILT AND SILT REMOVAL IN A NORTHERN PRAIRIE LAKE
C.K. BRASHIER, Dakota State College, Undergraduate School, *Madison, South Dakota* 57042

The objective of this project is to determine the amount of lake eutrophication due to siltation. A study of variations of mineral quality of lake water due to siltation from various watersheds will be made. Eutrophication elements (and biota) of silted late will be compared with those of relatively unsilted, but domestically polluted lake.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0365, EFFECT OF DREDGING ON THE NUTRIENT LEVELS AND BIOLOGICAL POPULATIONS OF A LAKE
C. CHURCHILL, Dakota State College, Undergraduate School, *Madison, South Dakota* 57042

The proposed research project is designed to evaluate changes in nutrient levels and biological populations in a shallow, warm water lake due to the removal of sediments by dredging. This project will be carried out in Lake Herman, Lake County, South Dakota. Lake Herman, 1350 acres in size, in 1968 had an average of 4-1/2 feet of water and six feet of sediments. Considerable data has already been gathered on the lake mainly through surveillance projects funded by OWRR and FWPCA.

Included in the investigation will be an analysis of environmental factors such as phosphorus, potassium, nitrogen, sodium, pH, temperature, dissolved oxygen, alkalinity (Ca, Mg), turbidity, phytoplankton, and zooplankton. A comparison of these data will be made between dredged and undredged parts of the lake, between Lake Herman and similar types of lakes, and during dredging and prior to dredging.

This project will be a phase of an overall program that involves the following: (1) a surveillance study of a heavily silted lake; (2) the prevention of silt from entering the lake; (3) the elimination of silt from the lake bottom; (4) the study of nutrient and biological changes in the lake during dredging; adn (5) a surveillance program for a long-term duration after dredging.

2.0366, SEDIMENT YIELDS FROM RANGELAND WATERSHEDS IN THE NORTHERN GREAT PLAINS
A.R. KUHLMAN, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Newell, South Dakota* 57760 (SWC-014-DNI-2)

OBJECTIVE. Obtain measurements of sediment yield from rangeland watersheds in western South Dakota and to develop procedures for estimating sediment accumulation in stockponds in this area.

APPROACH: Periodic surveys are made of sediment accumulations in 74 stockponds in western South Dakota. Precipitation is measured at each pond with small orifice storage gages. All watersheds have been surveyed for range site and condition and will be resurveyed every three years. The data will be analyzed to determine mean sedimentation rates and to determine if differences in soils or vegetation result in significant differences in the mean annual rates.

PROGRESS: Sediment yields from rangeland watersheds have been measured near Newell in western South Dakota. Topographic resurveys have been made of 15 stock ponds. The interval between surveys varied from 5 to 8 years. The mean erosion rate

from 9 watersheds on moderately coarse-textured soils was 0.69 tons/acre/year with a range of zero to 4.87 tons/acre/year. The mean yield from six watersheds on fine-textured soils was 2.65 tons/acre/year with a range of from 0.21 to 6.51 tons/acre/year. For the period (1958-69) mean annual runoff was 0.59 inches from the moderately coarse-textured soils and 1.48 inches from the fine-textured soils. High erosion rates were associated with high runoff, poor vegetation and bad land topography on a portion of the watershed.

SUPPORTED BY U.S. Dept. of Agriculture

2.0367, HYDROGEOLOGY OF A WELL FIELD
P.H. RAHN, South Dakota School of Mines, School of Engineering, *Rapid City, South Dakota* 57701

The area investigated was that of the well field of the University of Connecticut in the valley of the Fenton River. The measurements showed the effect of flow from the wells on streamflow. Under some conditions as much as one-third of the water pumped from the wells was stolen from the river via induced streambed infiltration.

An extension of this investigation was concerned with the effect of induced infiltration on water quality. In the valley of the Naugatuck River near Waterbury, Connecticut, well water was found to contain relatively high concentrations of sulfate and copper, derived from the river water. Bacterial contamination, however, was absent. These observations suggest that chemical pollution is the biggest danger to wells in river valleys.

The knowledge gained in this project can be used in planning the location of future water wells.

2.0368, RADIONUCLIDE UPTAKE BY MARINE ORGANISMS IN ARTIFICIAL POOL AND ELIMINATION OF RADIOACTIVITY
J. ROS, Ministerio De Comercio, *Madrid, Spain*

1. Study of radionuclide uptake by marine organisms in an artificial pool and elimination of radioactivity under natural conditions. 2. Behavior of radiosotopes concentrated in the surface layer of sediments under quasi-natural conditions.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

2.0369, CHANGES IN WATER QUALITY PARAMETERS OF RESERVOIRS DURING REGULATED FLOW CONDITIONS
F.C. LARSON, Univ. of Tennessee, School of Engineering, *Knoxville, Tennessee* 37916

Weekly sampling and testing is to be done at ten stations in Fort Loudoun Reservoir, Tennessee (a T.V.A. impoundment). The following tests will be made on all samples: The coliform count (membrane filter technique), pH, conductivity, dissolved oxygen, biochemical oxygen demand, apparent and centrifuged color, suspended solids, chlorides, iron, manganese, phosphates, ammonia N, nitrite N, nitrate N, and organic N. A portable continuous recording monitoring system will also be used in this investigation.

Inasmuch as the total organic loading on the reservoir will be greatly reduced this year, changes in water quality can be recorded and compared with previous results.

Additional information on iron and manganese build-up and eutrophication in a river-lake regime will be obtained and studied.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0370, ABSTRACT PREPARATION FOR THE WATER RESOURCES SCIENTIFIC INFORMATION CENTER
P.A. KRENKEL, Vanderbilt University, School of Engineering, *Nashville, Tennessee* 37203

The objectives of this project are: to serve the scientific and technical needs of scientists, engineers, and others interested in the field of Thermal Pollution with respect to available literature; to establish Vanderbilt University as an information retrieval center for the area of Thermal Pollution; to make this information available to the scientific community; and to supply copies of requested abstracted articles at a nominal cost.

The tables of contents of journals and selected articles for abstracting which appear to be pertinent will be examined. The articles will then be obtained by one of the abstractors, and the abstract prepared in accordance with the instructions given by the Water Resrouces Scientific Information Center. The abstractor then will submit the material to the investigator along with two copies of the article. The investigator will edit the abstract and examine the article to insure that it is worthwhile for inclusion in the Selected Water Resources Abstracts publication. Upon completion, the abstract is attached to a copy of the article and sent to the Water Resources Scientific Information Center. These articles are submitted twice monthly, 25 abstracts being presented at a time.

Our abstracting endeavors will include information on: chemical and physical aspects; effects of thermal pollution; means of prevention; economics of cooling water use; and beneficial effects of heated discharges.

In preparing abstracts for the Water Resources Scientific Information Center, a wide variety of material on thermal pollution is being collected. This material is on file on index cards filed by author and date of accession, and in full size. We anticipate that this file will become the most comprehensive library and document collection on thermal pollution in the nation.

2.0371, STATUS OF THERMAL POLLUTION AND RESEARCH NEEDS
F.L. PARKER, Vanderbilt University, School of Engineering, *Nashville, Tennessee* 37203

Specific Objectives: The specific objectives of this study are: 1. To compile an exhaustive bibliography on thermal pollution, including the effects of heat on chemical, biological and physical aspects of water quality, the effects of heat on waste assimilative capacity, alternative methods for the dissipation of excess heat from cooling waters, the hydrodynamics of heated water discharges, and the energy balance as related to the dissipation of heat from receiving waters. 2. After intensive review, to select the most meaningful and current references from the bibliography and subject these papers to critical review and summary. 3. To present a report derived from (2) which will contain the following items: a. Discussion of each topic in sufficient detain to give the reader insight into the current stage of development of that topic. b. Discussion of the major research needs in each problem area and an indication of the most fruitful approaches of these needs. c. Discussion of the existing and potential water quality problems due to heated discharges and their relationship to water pollution control requirements.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0372, SEPARATION OF SOLAR AND HEATED DISCHARGE EFFECTS
F.L. PARKER, Vanderbilt University, School of Engineering, *Nashville, Tennessee* 37203

When condenser cooling waters are discharged into shallow waters, it is sometimes difficult to determine that part of the temperature rise due to solar radiation and absorpton by water and river bottoms and that part due to the heated discharge. It is also difficult to determine whether or not the time profile of the temperature rise is materially affected by absorption of the bottom sediments and emergent rocks. When solar heating is significant, the measured cross-sectional temperature distributions may give mistaken impressions of the movement of the heated discharge. It would be beneficial to the analysis of induced temperature rises if these effects could be separated. To make a realistic assessment of the temperature rise due to absorption in the bottom sediments, basic information on the transmission of solar energy through water with various degrees of turbidity and uptake by sediments of different types will be needed. With this basic information, the amount of excess temperature rise and the resultant temporal displacement of the peak temperatures will be investigated. Field studies will be carried out to determine the validity of the results of the computer program which will predict

the temperature rise. Simultaneous dye and temperature studies will be performed to determine the path of the heated effluent. This project was begun in January 1970 and is scheduled for completion in September 1971.

2.0373, ANALYSIS OF THE STRUCTURE AND FUNCTION OF ECOSYSTEM IN THE DECIDUOUS FOREST BIOME

S.I. AUERBACH, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831

An integrated ecological research program carried out by investigators from Oak Ridge National Laboratory and a number of universities, as a part of the Analysis of Ecosystem component of the International Biological Program. The long-term goal of the program is to evaluate the impact of man's activities on regional complexes of ecosystem and to derive a fuller scientific basis for improvement of environmental quality through rational use of land and water. Specific objectives of the research in the Eastern Deciduous Forest Biome region include (a) elucidation of the productivity, rates of nutrient and energy flow, and other ecosystem parameters; (b) determination of rates of change, transfer pathways, and food chain kinetics in major ecosystem types in eastern U.S.; (c) determination of the functional roles of animals and microorganisms in maintaining system stability; (d) determination of the rates and efficiencies of forested, agricultural, and aquatic ecosystems for cycling of nutrients and other mineral elements; (e) understanding of the influence of terrestrial ecosystems on water quality and on aquatic productivity; (f) evaluation of the actual and potential efficiency of natural and managed ecosystems for utilization and conversion of solar energy. During the initial phases, the research will be oriented chiefly toward the basic major processes that govern ecosystem structure and function. Modeling and systems analysis will be employed to redirect field activities in the course of the investigation and to provide a continuing synthesis of results. Field research and modeling activities will be concentrated at five sites: Oak Ridge National Laboratory Reservation, Tennessee; Lake Wingra, Madison, Wisconsin; Lake George, N.Y.; Coweeta Hydrologic Lab., Franklin, N.C.; and the Research Triangle area, North Carolina.

2.0374, WATERSHED AQUATIC HABITAT INTERACTIONS

D.J. NELSON, U.S. Atomic Energy Commission, Oak Ridge National Lab., *Oak Ridge, Tennessee* 37831 (W-7405-ENG-26)

The purpose of this research is to determine the factors and mechanisms governing the movement of water, mineral elements, and organic detritus from the landscape into surface streams. Knowledge of the fate of energy and mineral elements in production processes in both terrestrial and aquatic environments will contribute to our optimum utilization of these ecosystems for human welfare. Maintenance of terrestrial productivity depends on the coaction of biological and physical factors influencing the cycling of mineral elements on the landscape and flow of materials into the stream. The loss of material from the landscape determines water quality and productivity within the stream environment. The Walker Branch Watershed is considered as an input-output system with water as the vehicle for dissolved and suspended materials. Materials come into the basin as dry fallout, rainfall and rain-scavenged matter and enter biogeochemical cycles on the landscape before being transported downstream. The interactions between the biotic and abiotic features of the environment are being studied by an interdisciplinary team of biological and physical scientists. The final objective of these studies is to translate the experimental results gained from a small, controlled drainage basin into preceptive predictions of the potential impact of management alternatives on the total ecosystem.

Results: Water and material balance studies are continuing and one of the most striking features is the cyclical input of dry particulate matter. Soils have been characterized physically and chemically. Stand tables were developed from the forest survey data and forest stands were ordinated by use of principal component analysis. Calcium movement from leaf litter, tagged with calcium-45 was less than 1 meter into the soil profile after 18 months. The standing crop and productivity of periphyton were determined with a phosphorus-32 release to the creek. Sampling of stream benthic organis for community diversity, growth rates, emergence, and life history information was completed.

SUPPORTED BY U.S. Atomic Energy Commission

2.0375, METHODS OF CONTROL OF NITROGEN AFFECTING THE QUALITY OF UNDERGROUND WATER SUPPLIES IN RUNNELS COUNTY, TEXAS

P.E. HUDSON, Radian Corporation, *Austin, Texas* 78758

The Radian Corporation is conducting research to determine the source of nitrate pollution in Runnels County and will develop plans and implement methods for controlling nitrates affecting the quality of underground water supplies in the County. Included in the study are various test methods to determine the source of nitrogen, plus the collection, compilation and analysis of data related to the objectives in the project area. The study includes a determination of the location and extent of fresh-water bearing units and the chemical and biological quality of the water they contain. The report on the results of the study will contain recommendations for the elimination and/or control of the nitrogen problem which presently exists as well as preventing or minimizing further nitrogen contamination problems.

A 'First Phase' study, which consisted principally of inventorying and sampling water wells and measuring ground water levels throughout the county and studying the geology and hydraulic characteristics of the ground water aquifers was completed September 15, 1970 and culminated in a report. The project is currently inactive.

An application has been submitted to the Environmental Protection Agency for a R&D grant to provide for an extensive study of this problem. The application is currently being reviewed by the Environmental Protection Agency.

SUPPORTED BY Texas State Government - Austin

2.0376, PERMIAN BASIN - ORIGIN OF SALINE WATER DISCHARGE

P.R. STEVENS, U.S. Dept. of the Interior, Geological Survey, *Austin, Texas* 78701

Natural brine discharging through seeps, springs and salt flats contaminates the water in many streams in the Permian Basin. Previous investigations have ascribed this salt condition to the circulation of ground-waters through salt-bearing rocks and ultimately the discharging of the salt water in topographic low areas. Another hypothesis postulates that brine underlies the entire Permian Basin at a relatively shallow depth; the brine is overlain by relatively fresh water; the interface describes a surface of hydrodynamic equilibrium which also functions as a impermeable boundary separating the brine and fresh water into essentially discrete hydraulic units. The objective is to study all aspects of the occurrence of brine in this area and suggest measures that might alleviate the condition.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0377, PHYSIOCHEMICAL RESPONSES OF RIVERS TO NATURAL AND MANMADE ENVIRONMENTAL CHANGES

E.F. GLOYNA, Univ. of Texas, School of Engineering, *Austin, Texas* 78712

The proposed research plan involves various interaction studies using closed ecosystems and a 'Model River.' The Objective is to evaluate the transport mechanisms which are operative in the waterway. Specifically, it is desired to develop a better understanding of the cycling effects of nutrients and conservative materials under various environmental conditions and to incorporate these uptake, release, and cycling effects into the total transport model. To accomplish this it is necessary to develop better approximations of the physiochemical system of a fertile waterway.

2.0378, PRINCIPLES, FACILITIES AND SYSTEMS FOR GROUND WATER RECHARGE--SOUTHERN PLAINS
A.D. SCHNEIDER, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Bushland, Texas* 79012 (SWC-012-EBUS-1)

OBJECTIVE: Develop methods, principles, facilities, and economical systems for conserving surface water supplies by ground water recharge including water clarification, wells, and surface spreading.

APPROACH: Water clarification by coagulants and flocculants is studied in the laboratory. Economical field water clarification systems are then developed and tested. Recharge wells, clogging, redevelopment, new drilling methods are studied by analog models, physical models, and field tests. Ground water pollution by recharge is studied in the laboratory and field and methods developed for control.

PROGRESS: Preliminary field and laboratory studies indicated the feasibility of recharging the Ogallala aquifer through the Pleistocene pluvial sediments when the slowly permeable Pullman clay loam or Randall clay is removed. Two basins, 0.1 acre in area, were excavated approximately 3.5 feet to expose the caliche and underlying sediments. Twenty acre-feet of well water was applied to the first basin in 46 days with a maximum percolation rate of 7.0 feet per day occurring at the end of the test. A mixture of well and runoff water, containing an average of 189 p.p.m. suspended solids, was used in the second basin. During the 66-day test period, 14.9 acre-feet of water was recharged with a final percolation rate of 1.5 feet per day. Deep percolation into the Ogallala aquifer 175 feet below the basin was clearly evidenced by a sharp rise in the water table. Recharge basins have a distinct advantage over recharge wells (or shafts) because the studies show that initial infiltration rates can be restored by removing the sediment sealed surface. To study the fate of herbicides introduced into recharge wells, picloram, atrazine, and trifluralin were added to water that was injected into a dual-purpose well for 10 days at 360 g.p.m. The ground-water mound created by recharging was allowed to dissipate for 10 days, and then the well was pumped for 12 days at 570 g.p.m. Ninety-three percent of the recharge water was recovered, and this water contained more than 90 percent of each herbicide injected.

SUPPORTED BY U.S. Dept. of Agriculture

2.0379, WATER QUALITY HYDROLOGY OF LANDS RECEIVING FARM ANIMAL WASTES
D.L. REDDELL, Texas A & M University System, School of Agriculture, *College Station, Texas* 77843

Livestock feeding operations are growing in size and are concentrating large supplies of feed and animals into smaller areas. Because the disposal of animal wastes in surface waters is undesirable, land disposal of manure is being advocated. However, with the increased use of large commercial feeding operations, the practice of land disposal of animal wastes presents two problems. The first problem concerns possible pollution of surface water and groundwater by the spreading of such wastes onto the land. The second problem concerns the nitrate accumulation which may occur in soil and water adjacent to land disposal systems.

This study is directed towards providing answers to such problems by carrying out the following program: 1. Field plots will be established with varying manure application rates. The physical, biological and chemical quality of surface runoff and deep percolation will be determined and used to evaluate the potential pollution from land disposal of manure. 2. Laboratory investigations will be utilized to determine the nature of the nitrate problem. Effects on the nitrogen cycle created by placing manure deep into the soil profile will be studied. Also, soil conditions for promoting dentrification will be examined.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0380, GEOCHEMICAL BEHAVIOR OF URANIUM AND THORIUM SERIES NUCLIDES
W.M. SACKETT, Texas A & M University System, School of Geosciences, *College Station, Texas* 77843 (AT(40-1))

A continuation of studies aimed at understanding the behavior of uranium and thorium and their radioactive daughters in natural environments is proposed. Emphasis is being placed on (1) a study relating the high uranium in present day runoff from the U.S.A. to extensive phosphate fertilizer application to the land surface, (2) the carbonate 'uranium sink' in the Gulf of Mexico and (3) the Th-228 and Th-234 distributions in the ocean. Additional work is anticipated on the behavior of uranium-thorium series nuclides during weathering, stream and river transportation and deposition in near shore and deep ocean environments.

Uranium is determined by delayed neutron counting after activation. The amount and isotopic composition of uranium, thorium and protactinium are determined by carrier free separation, isotope dilution and alpha spectroscopy techniques.

RESULTS: A reasonably good balance of uranium between pre- fertilizer input and removal by shallow water carbonate deposits in the Gulf of Mexico; a direct relationship between phosphate and uranium in 27 fertilizers randomly sampled from a collection of 4000 and Th-234, Th-228 distributions that may give settling rates for suspended material in the ocean.

SUPPORTED BY U.S. Atomic Energy Commission

2.0381, EFFECTS OF FURROW, SPRINKLER AND SUBIRRIGATION METHODS ON POTENTIAL POLLUTION OF GROUNDWATER BY NITRATES AND OTHER SOLUTES
C.W. WENDT, Texas A & M University System, School of Agriculture, *College Station, Texas* 77843

This project will consist of a series of field and laboratory experiments and data interpretation to determine the effects of subirrigation, conventional irrigation methods and nitrogen fertilizers on underground water pollution. Laboratory studies will determine the applicability of existing models for water and ion movement to the soil and water conditions of the test site, and the rate of nitrogen releases from various mixtures of slow release materials and of materials treated with nitrifying bacteria inhibitors. Field studies will be used to determine movement of water, nitrate and other salts as influenced by amount and method of irrigation water application and amount and source of applied nitrogen, coefficients for the predictive ion movement model as influenced by irrigation and fertilization variability, and economics of fertilization practices and of the installation, operation, and maintenance of furrow, sprinkler and subirrigation systems. Quantitative effects of irrigation and fertilization methods on the potential pollution of underground water by nitrates and other salts, effects of the various practices on crops yield and quality, and the economic feasibility of practices reducing potential pollution will be determined. This study will begin June 1970 and end February 1974, with the work being conducted at Lubbock and Munday, Texas.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0382, NATURALLY OCCURRING TASTES AND ODORS IN WATER SUPPLIES
J.K. SILVEY, North Texas State University, School of Arts, *Denton, Texas* 76203

The taste and odor compounds produced by the aquatic actinomycetes may be satisfactorily concentrated by employing freeze-stir techniques. Samples produced by this method may result in approximately 2,000 times the original concentration of the organic components responsible for the tastes and odors. Low temperatures maintain the compounds in original chemical composition without altering the molecular structure. Gas chromatographic studies of the concentrates from laboratory-produced cultures indicate that six components are involved in the typical earthy, musty odors produced by these organisms. NMR investigations demonstrate that all compounds are neutral and polar. Studies on taste and odor components from the water sup-

plies subjected to the same techniques demonstrate that the compounds available in raw water are chemically identical with those produced by laboratory techniques. With the above information available, the use of gas chromatography with the proper instrumentation now available to use the mass spectrometer should make identification of the compounds relatively assured.

2.0383, EVALUATION OF ENGINEERING PROJECTS AND ESTUARINE DATA (ESTUARINE PROGRAM)
R.J. HOOGLAND, U.S. Dept. of Commerce, Natl. Oceanic & Atmos. Admin., *Galveston, Texas* 77552

Estuarine-dependent species of the Gulf of Mexico coast comprise several of the nation's most valuable fishery resources. If the nursery grounds in the estuaries are to be preserved, it is essential that the estuarine habitat of these species be protected during and following construction of water-development projects in upland basins, estuarine systems, and coastal marshes. The increasing number, as well as complexity, of construction projects require a detailed understanding of estuaries.

It is the purpose of this project to (1) assist the Branch of River Basin Studies (BSFW) by reviewing all proposed construction and water- development projects affecting western Gulf estuaries and, when warranted, recommended remedial measures to reduce adverse project effects; (2) where practical, recommend changes in water-development projects whereby the habitat would be enhanced for the fishery resources; (3) inventory, organize, and keep current and published and unpublished data related to western Gulf estuaries; and (4) recommend basic research needed for protecting estuarine fishery resources.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0384, ECOLOGY OF WESTERN GULF ESTUARIES
W.L. TRENT, U.S. Dept. of Commerce, Natl. Oceanic & Atmos. Admin., *Galveston, Texas* 77552

Demands upon water resources along the coast of the Gulf of Mexico are rapidly altering the estuarine environment. These combined alterations disturb the integrity of large estuaries to the extent that entire biological systems may be significantly affected. Basic to an evaluation of the effects of estuarine alteration is knowledge of the interrelations of factors, such as nutrients, bottom types, marine organisms, and vegetation.

Project objectives are to (1) compare the productivity of natural estuarine habitats with areas altered by dredging, spoiling, bulkheading and filling; (2) determine practical methods for rehabilitating altered habitats so that productivity can be reestablished; and (3) determine management procedures for maintaining or increasing the productivity of estuarine areas.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0385, VARIATION OF URBAN RUNOFF QUALITY WITH DURATION AND INTENSITY OF STORMS
D.M. WELLS, Texas Technological University, Water Resources Center, *Lubbock, Texas* 79409

This project will collect and analyze samples of stormwater runoff from an urban residential area to determine the quality of runoff and its variation with duration and intensity of storms. Samples collected will be analyzed for total solids, suspended solids, volatile suspended solids, BOD, COD, total nitrogen, and phosphorus. Selected portions of the runoff will be collected and treated in lab-scale model treatment plants to determine whether or not such treatment is economically feasible. An existing dense network of rain gages on the 1.5 square mile watershed will yield information regarding the areal variation of rainfall over a small area, and periodic sampling of runoff by an automatic sampling device will indicate the feasibility of segregating the most heavily polluted portion of storm runoff for separate treatment. The project will be started July 1, 1969, and will continue through August 31, 1971.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0386, EFFECT OF USING RUNOFF WATER IN RECHARGE WELLS-HIGH PLAINS AREA
J. VALLIANT, High Plains Research Found., *Plainview, Texas* 79072

The purpose of the study is to evaluate the effect of recharging with runoff water on the Ogallala aquifer and the ground water quality. By using pumping tests, the effect of suspended solids contained in recharge water upon the Ogallala aquifer are being determined for the area under study. The effect on transmissibility, specific yield, and other characteristics are being evaluated and determinations made as to whether additional desilting methods may be required to avoid clogging the aquifer. The study includes a determination of the movement of pesticides, herbicides, bacteria and other agricultural chemicals through the aquifer. A determination is being made as to whether the playa lake waters recharged are compatible with the ground water with respect to calcium carbonate equilibrium.

SUPPORTED BY Texas State Government - Austin

2.0387, SEDIMENT PRODUCTION, YIELD AND DELIVERY RATE IN RELATION TO CLIMATIC AND WATERSHED CHARACTERISTICS
R.W. BAIRD, Blacklands Expt. Watershed, *Riesel, Texas* 76682 (TEX08023)

OBJECTIVE: Determine the amounts and sources of sediment yields from small agricultural watersheds as affected by land use and treatment.

APPROACH: In the Blacklands near Riesel, measured runoff will be sampled and sediment yields computed by storm periods from six watersheds with different treatments and sized from 16.3 to 4,380 acres. Two are paired watersheds with major differences in treatment.

PROGRESS: During 1968 sediment yields were obtained from eight agricultural watersheds ranging in size from 16.3 to 4,380 acres. Weighted rainfall on the watersheds was from 46.70 inches to 51.18 inches. The 31-year average for the area is 33.16 inches. Monthly rainfall was above the average for all months except August, October, and December. Yearly runoff ranged from 11.13 inches to 18.34 inches. No storms of large amounts or unusually high intensities occurred. Sediment yields ranged from 0.03 to 0.24 tons per acre per inch of runoff. Sediment yields were much lower than in 1965 when runoff amounts ranged from 9.73 to 15.68 inches. In 1965, high intensity rainfall during thunderstorms in March and May when areas with spring planted crops were nearly bare of vegetation caused much larger sediment yields than those of 1968. The 1968 results show the major effects of crops, land use practices, and time of intense storms on sediment yields.

SUPPORTED BY Texas State Government - Austin

2.0388, SEDIMENT YIELD IN RELATION TO WATERSHED AND CLIMATIC CHARACTERISTICS IN THE WESTERN GULF REGION
J.R. WILLIAMS, Blacklands Expt. Watershed, *Riesel, Texas* 76682 (SWC-014-ETEM-3)

OBJECTIVE: Determine sediment yields, sources, and sediment accumulation in floodwater retarding structures. Develop prediction equations and routing technique.

APPROACH: Sediment yields are measured by sampling runoff from 10 Blackland watersheds with different treatments and areas of 5.2 to 4380 acres. In the Edwards Plateau, sediment is measured by surveys of 5 floodwater retarding structures with watershed areas of 686 to 10,787 acres. Develop routing procedures, temporal sediment distribution will be correlated with temporal flow distribution and flood routing procedures modified to include sediment. A prediction equation relating sediment to land use and treatment, and storm and watershed characteristics will be developed for use on ungaged areas.

PROGRESS: A technique was developed to predict sediment yields from small Blackland watersheds at Riesel, Texas. Factor analysis was used to reduce 27 variables to six important and rela-

tively independent factors for predicting average sediment concentrations for individual storms. The six factors are: weighted rainfall intensity; amount of rainfall; peakedness ratio; portion of watershed area unterraced but cultivated; product of the portions of cultivated area and Blackland area; and hypsometric integral. Prinicipal components regression was used to relate these six factors to sediment concentration. The resulting equation explained 63% of the variation in sediment concentration and had physically interpretable coefficients since it was developed from relatively independent factors. Sediment accumulations in four detention reservoirs in the Lowrey Draw watersheds were quite low during 1961-68. The average sediment concentration during this eight year period of near normal climatic conditions ranged from 483 to 1176 ppm for four rangeland watersheds. The sediment accumulation ranged from 0.009 to 0.019 acre-feet per square mile per year. If sediment continues to accumulate at the 1961-68 rate, the average time required to fill the sediment pools would be 1600 years. A comparison of concentrations of suspended sediment collected with depth-integrating and dip samplers showed significantly greater concentrations for the integrated samples when sampling fine-grained sediments. Concentrations of depth-integrated samples were 1.02 greater than concentrations of dip samples.

2.0391, MINIMIZING SOIL AND WATER POLLUTION FROM FERTILIZERS AND IRRIGATION WATERS--RIO GRANDE PLAIN
G.W. LANGDALE, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Weslaco, Texas* 78596 (SWC-027-EWES-5)

OBJECTIVE: Determine the NO(3)-N and NO(2)-N enrichment in drainage effluents and ground waters from nitrogenous fertilizers; and the frequency where irrigation waters are used to remove salts from moderately saline soil profiles of the Lower Rio Grande Valley.

APPROACH: Anion 'pulses' through heterogeneous soil profiles to drainage effluents will be measured as function of irrigation water and applied N-fertilizer. Nitrogenous contaminants, NO(3)-N and NO(2)-N, will be measured concomitantly with saline contributing anions and cations to evaluate their effect on the movement of former through soil profiles to drainage effluents. kates of applied N-fertilizer and irrigation water will be used to control NO(3)-N and NO(2)-N movement or enhance denitrification.

PROGRESS: Movement of residual-N (control) and N-fertilizer (448 kg/ha) through Hidalgo clay loam soil profiles to drain lines 2.4 m deep in an established citrus orchard was studied between April and December 1969. Approximately 50% of the N-fertilizer was accounted for as NO(3)- N between the 1.0 to 2.4 meter profile depth in December. Control plots contributed an average of 7.33 kg/ha of NO(3)-N to drainage effluents. An additional 1.82 kg/ha of N-fertilizer was accounted for in these effluents. Chloride-NO(3)-N relationships were developed since soil salinity may affect the nitrate content in the soil. The ratio of Cl:NO(3)-N removed in drainage effluents was 56:1 with a correlation coefficient of 0.93. Judicial use of applied N-fertilizers and irrigation water for citrus production appears to permit adequate salt leaching without the occurrence of excessive NO(3)-N concentrations in drainage effluents.

2.0392, RADIOECOLOGY OF THE KUCUK CEKMECE LAGOON
Y.M. UNLU, Cekmece Nucl. Res. & Tr. Ctr., *Istanbul, Turkey*

The Kucuk Cekmece Lagoon will likely receive some radioactive effluents from the Cekmece Nuclear Research Center in the near future. This study is concerned with radioactivity levels in the Kucuk Cekmece lagoon. Some biological factors concerning this region are: Geographical position 41 degrees OO'N-28 degrees 43'E, max. depth 25 m, area 15.22 km2 , salinity 37 to 6.85 parts per thousand, temperature 25 degrees C- 6.8 degrees C, phosphorus inorganic phosphate content max. 26.2 mg/m3, aquatic marine life.

The range of radioactivity studied over a two-year period from February 1968 to January 1969 was on average 8.2 pCi/l and a tenfold increase in activity 87.98 pCi/l was detected in 1970. Therefore in order to avoid unpleasant surprises it is necessary to determine the natural radioactivity level in the lagoon's biota and sediment and especially the pathway of selected radionuclides in economically important organisms of the lagoon (ecosystem).

The result obtained from the above research project will serve to describe the background information for the present situation of the lagoon and will be benefitial for effective future control. Experimental radioecology will be the central theme of the research planned. The influence of various environmental factors on the ability of these organisms to concentrate radionuclides will be studied.

2.0395, QUALITY OF IRRIGATION RETURN FLOW
L.G. KING, Utah State University, School of Engineering, *Logan, Utah* 84321

Irrigation return flow constitutes a very large portion of the water influent which reaches the streams of the Western United States. Since these influents invariably bear a load of dissolved solids and can contain nutrients, trace elements, and biocide residues, their impact from a pollution point of view is of major concern in the entire Western United States.

The primary objective of this project is to conduct research on the problems that affect the quality of irrigation return flow.

2. WATER QUALITY

This is to be accomplished by studies in four areas: (1) precipitation mechanisms in soils as they affect water quality - this phase will be concerned with the changes in the quality of water, as it moves through soils, as a result of precipitation of calcium carbonate; (2) to develop information for predicting the changes in the salinity content of soil and drainage water resulting in changes in the quality of irrigation water and in irrigation management; (3) managing water in the soil plant matrix to control the quality and quantity of return flow; and (4) contamination of surface and drainage waters with soil and foliar herbicides - there will be special emphasis on heavy rates used on canal banks, drains, waterways, etc.

During this year, a major part of the research will be conducted in the field on a farm in the Ashley Valley near Vernal, Utah, within the Colorado River Basin. The farm will be provided with a tile drainage system, sprinkler system, and intensive instrumentation to monitor the movement and quality changes of water from its application to its discharge from the drainage system.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0396, THE EFFECTIVENESS OF WATERFOWL IN CARRYING PATHOGENIC MICRO-ORGANISMS
J.B. LOW, Utah State University, State Coop. Wildlife Res. Unit, *Logan, Utah* 84321

Waterfowl because of their migratory habits fly from one water source to another in their early or seasonal movements. These birds are potential carriers of disease producing micro-organisms because of the common practice of Utah towns and cities of disposing of their sewage into streams of water. These streams usually drain into lakes or marsh lands which are utilized by the watefowl for nesting, brood rearing, and other normal activities. There is a large accumulation of organic sewage in these areas and may be a source of pathogenic organisms. Because waterfowl are in contact with this raw sewage they will be investigated as to the role they may play in the dissemination of micro- organisms.

The work will be carried out under the following objectives: (1) To determine the incidence of indicators of pathogenic micro-organisms present on waterfowl in western marshlands. (2) To study the effectiveness of waterfowl to directly discriminate organisms by carrying them on feet, feathers, and other body parts. (3) To determine the organisms available for transmission by waterfowl. (4) To determine the longivity of contamination of waterfowl by micro-organisms attached to feet, feathers and other parts of waterfowl.

SUPPORTED BY Utah State University

2.0397, LEAD SHOT, ITS SETTLEMENT, OXIDATION, AND AVAILABILITY TO WATERFOWL
J.B. LOW, Utah State University, State Coop. Wildlife Res. Unit, *Logan, Utah* 84321

This research is a 6-year study designed to accomplish the following objectives: (1) To determine the rate of settlement of lead pellets through the marsh soil. (2) To determine the rate of oxidation and decomposition of lead pellets in typical saline marsh soils. (3) To determine the availability of lead shot pellets to waterfowl in a 'typical' waterfowl feeding area. (4) To ascertain the general distribution of lead pellets in a typical western marsh and their availability to waterfowl.

The area selected for study is a part of the Unit 2-A located on the Bear River Migratory Bird Refuge at Brigham City, Utah

The experimental area is 23 feet by 11 feet and is composed of 24 plots with 4 sub-plots per plot (one sub-plot for each shot size).

To facilitate the deposit and recovery of the lead pellets the plots were arranged into rows, producing six rows of four plots each, with walkways between and around the rows.

Each fall, four of the main plots will be sampled. This will provide 16 sub-plots with 4 sub-plots for each sized pellet; if all pellets are recovered there will be 200 pellets for each sized pellet.

SUPPORTED BY Utah State University

2.0398, WATER QUALITY OF HYRUM LAKE AND ITS RELATIONSHIP TO ALGAL BLOOMS
R.I. LYNN, Utah State University, Graduate School, *Logan, Utah* 84321

The proposed research plan involves laboratory and field studies to determine, identify and locate the source of pollutants which we believe to be the cause of a recurrent algal bloom in Hyrum Lake. The proportion of the bloom during the late summer and early fall of 1969 resulted in a 75% decline in usage of the lake by boaters, skiers and swimmers of that year. Our basic approach will be to analyze the physical, chemical and microbial components and processes within the lake and to judge from these results a means of preventing or reducing the severity of future algal blooms. The bloom organisms has been identified as 'Aphanazemenon flosaquae', a member of the blue-green algae, some strains of which have been shown to be toxic to numerous animals. This aspect of the problem increases our desire to reduce the intensity of the bloom as soon as possible.

Laboratory and field studies will employ the following methods: 1. Using water collected from Hyrum Lake, during various times of the year, we will supplement with nitrogen and phosphorus singly and in combination to determine which, if either, is the limiting factor for growth of the 'Aphanazemenon' in the lake. 2. We will also monitor the numbers of the bloom organism in Hyrum Lake. 3. We will also monitor the relative efficiency of photosynthesis of the algae of the lake as part of the coordinated effort to establish the series of events preceding the appearance of the algal bloom. 4. Laboratory and field data will be correlated to pinpoint sources of nutrient input to the lake and suggestions made to moderte or eliminate the same.

2.0400, A STUDY OF THE BIOLOGICAL, CHEMICAL AND PHYSICAL NATURE OF WATER QUALITY FACTORS UNDER UTAH CONDITIONS
J.M. NEUHOLD, Utah State University, Utah Ctr. for Water Resour., *Logan, Utah* 84321

The characteristics and relationships of water quality factors pertinent to short, snow-fed mountain streams feeding to desert floors will be studied. Consideration will be given to: 1) watershed contamination 2) irrigation return and 3) domestic and industrial pollution. The relationship of the contaminant to volume of flow, rate of degradation and subsequent incorporation into the aquatic biomass will the matter of primary concern. Contaminant cycling, sedimentation and physical change will also be studied. The system under study will lend itself to model construction in terms of the environmental, physical, chemical and biological effects on contaminants. The information for such a model will be obtained from field observations and from experiments conducted on excised portions of the environment.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0401, THE KINETICS AND ENERGETICS OF ADSORPTION AND DESORPTION OF PHOSPATE FROM SOIL MINERALS
R.L. SMITH, Utah State University, School of Agriculture, *Logan, Utah* 84321 (AT(11-1)-1392)

The objective of this proposal is to determine the kinetics and energetics of phosphate desorption from solid phase CaCo sub 3 by evaluating the activation energies of both adsorption and desorption along with the pertinent thermodynamic functions. The literature reveals only one study wherein the activation energies of desorption of phosphate were obtained from natural soils. These type of data are important because they provide an index of the energy input required in a system before phosphate ions are released from the sorbed state. This study not only has great implications in terms of phosphate pollution of surface waters but it also provides data useful in the availability of soil phosphate to plants. The procedure is to determine the rate constants of both adsorption and desorption at 3 temperatures; 10 degrees, 20 degrees and 30 degrees. How these rate constants vary with temperature will allow the activation energies to be evaluated. How the adsorption and desorption isotherm varies with temperature also allows the calculation of the differential heats of adsorption. The kinetics and thermodynamic functions will be measured at various surface coverages to ascertain the variation of adsorption site energy on the surface of calcium carbonate

SUPPORTED BY U.S. Atomic Energy Commission

2.0402, POLLUTION AS A RESULT OF FISH CULTURAL ACTIVITIES

R.N. HINSHAW, State Div. of Wildlife Resour., *Salt Lake City, Utah* 84116

Fish hatchery effluents, according to recent literature, have not been evaluated as sources of pollution. With large numbers of hatcheries in the Nation, this problem should no longer be overlooked. So a proposal was submitted and accepted by the FWPCA to determine if fish cultural activities were indeed polluting receiving waters.

Consequently, a sampling program on four State hatcheries, one commercial and one Federal hatchery was begun to determine characteristic water chemistries on inflow, effluent, receiving water above, 100 feet below, and 1000 feet below hatchery outfalls. Parameters sampled bi-weekly include B.O.D., MPN coliform, dissolved oxygen, pH, carbon dioxide, hardness, temperature, M.O. alkalinity, specific conductance, nitrates, nitrites, ammonia, turbidity, settleable, suspended and total dissolved solids. 'Standard Methods' were used throughout except where modified by the Hach Company for use with their Engineer's Chemical Kit.

Bottom fauna analyses are being used to assist in evaluating the influence of hatchery wastes on receiving waters.

The sampling programs for water chemistry and bottom fauna will terminate in October 1969 and March 1970, respectively. The water will have been analyzed chemically for fifteen months, and bottom fauna analysis will provide monthly data for a year.

It is anticipated that these examinations will provide sufficient information to assess the levels of pollution. If the data demonstrate that these operations are harmful to beneficial uses downstream, abatement and preventative measures will be undertaken to correct existing problems.

2.0403, REMOVAL OF DISSOLVED CONTAMINANTS FROM MINE DRAINAGE

J.D. MILLER, Univ. of Utah, School of Engineering, *Salt Lake City, Utah* 84112

Pollution from mine drainage is a serious problem in areas where substantial coal and metal mining have been carried out. Effective treatment of such drainage has not been achieved in most instances. Neutralization of these effluents with limestone followed by precipitation of the metal hydroxides has been found to be impractical, primarily from the standpoint of liquid-solid separation. Other approaches are required for a solution to this problem.

One technique that appears attractive and that should be studied is the removal of such contaminants as iron, aluminum, and other metal ions by their adsorption on inexpensive disposable substrates, such as mill tailings. Important parameters that will be investigated are: concentration of contaminant, pH of solution, surface area and type of substrate, and temperature.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0404, NUTRIENT BUDGETS, RECYCLING, AND WATER TRANSPORT IN LAKE CHAMPLAIN

E.B. HENSON, Univ. of Vermont, School of Arts, *Burlington, Vermont* 05401

The objective of this study is to begin obtaining reliable measures of the mineral budgets of Lake Champlain. Water samples are to be collected from the major tributaries of Lake Champlain on a regular schedule along with measures of stream discharge. Curves will then be constructed from each watershed in an attempt to associate mineral loading with discharge. The mineral input into the lake will be calculated on a monthly basis. The total load leaving the lake through the outlet will also be measured to balance the nutrient budget equation.

Water transport passing several transects across the lake will be measured, and the total mineral loading measured to determine the rate of transport through the lake.

Cycling of these mineral components within the lake will be approached by examining the concentrations, and changes of concentrations, in each trophic level.

Parameters to be measured are: the ions of Ca, Mg, Na, K, bicarbonate, carbonate, phosphate, nitrate, and Cl. Also, conductivity, dissolved oxygen, B.O.D., and total organic matter.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0405, DDT IN SNOW FALLEN AT HIGH ALTITUDE SINCE 1950

C.S. HOUSTON, Univ. of Vermont, School of Medicine, *Burlington, Vermont* 05401

Snow cores will be obtained by snow augur drilling at the site of an established laboratory at 17,500 feet on Mt. Logan, Yukon Territory. Snow which has fallen over the past twenty years will be obtained and its date of fall approximately dated. The melted samples, in approximately three-year aliquots, will be returned to FWQA laboratories for analysis for DDT and other materials. The hypothesis is that such materials can have reached this high and isolated place only through fallout from the stratosphere.

The work will be done on Mt. Logan and analyses done in Cincinnati.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0406, SEDIMENT YIELD FROM AGRICULTURAL WATERSHEDS IN NEW ENGLAND

S.H. KUNKLE, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Danville, Vermont* 05828 (SWC-014-ADA-1)

OBJECTIVE: Obtain, assemble, and report data on the rate, quality, sources, and types of sediment transported in steep mountainous streams; relate sediment yield to land use, sediment properties, and hydraulic parameters.

APPROACH: Suspended sediment samples are taken at a number of gaging stations. Total load measurements will be made by measuring the accumulation of sediment in settling pools and measuring the suspended outflow from the pool. Movement of large particles is made by marking and accurately placing stones in channel reaches and periodically checking for movement.

PROGRESS: Surveys have been made of sediment accumulation in 9 weir ponds for drainage areas ranging from 116.5 acres to 16.8 square miles. However, the data are not yet analyzed. Three farm ponds in New Hampshire were surveyed to supplement the watershed data. 29,500 feet of bank along the Winooskie River from Essex Junction to Richmond, Vermont, was resurveyed to evaluate treatments of brush matting and riprapping established 25 to 30 years ago. Maximum deposition occurred at 8 to 9 feet above mean low flow stage. Bank deposition ranged up to 24 inches and overbank deposition up to 40 inches. In most respects the Winooski Project was successful in that seriously eroding banks were repaired and total erosion was reduced.

SUPPORTED BY U.S. Dept. of Agriculture

2.0407, URBANIZATION AND ITS EFFECT ON STREAM TEMPERATURE

E.J. PLUHOWSKI, U.S. Dept. of the Interior, Geological Survey, *Arlington, Virginia* 22209

2. WATER QUALITY

Man's impact on the hydrologic environment has received greater attention in recent years. Such factors as increased storm runoff, loss of valuable top soil, stream and atmosphere pollution have come under scrutiny owing to their rather obvious undesirable effects. Aside from large scale isolated instances of thermal pollution, however, little has been done to assess man's influence on the thermal patterns of streams. Alteration of the natural hydrologic environment of a stream may affect its heat energy balance causing substantial changes in water temperatures.

Five streams with varying degrees of urbanization in their drainage basins have been selected for intensive study. Connetquot River in central Long Island was chosen as a control for comparison purposes. This stream flows through a hunting preserve and is essential in its natural state. Five sites were selected along each stream and water temperatures obtained at each site. A statistical analysis employing a randomized block or latin square design will be utilized to test for significance between sites. Stream reaches yielding significantly different results will be subjected to an intensive field reconnaissance to isolate the cause of the anomaly.

An energy-budget approach will be utilized to assess the importance of urbanization factors on the overall flux of energy. Owing to the profound effect of certain meteorologic parameters on the heat balance it is likely that most studies will be restricted to periods of not less than 7 consecutive days. The most important factor in the energy budget is insolation which is being measured directly by placing a pyranometer just above the water surface of the control stream.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0408, EFFECTS OF DEICING COMPOUNDS ON VEGETATION AND WATER SUPPLIES
R.E. BLASER, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (VA-0808017)

OBJECTIVE: Investigate deicing salt effects on soils, plants, and water resources, and do an interpretation and review of the literature.

APPROACH: Investigate salt movement by depth and distance from roadsides and associate with plant morphological and physiological characteristics; study rate of salt absorption by plants; their salt tolerance and ion retention by soils.

PROGRESS: Although there are indications that build up of salts in them is not immediately hazardous to man, animal, and fish, roadside vegetation appears vulnerable. Studies on several deciduous and evergreen trees and shrubs to sodium and calcium chlorides in Virginia showed plant injury being associated with the amount of salt applied. The degree of injury caused by sodium and calcium chlorides varied among species. Salt tolerances of several deciduous and evergreen trees and shrubs have been evaluated and are now available. Research with silver maple on a Vergennes soil located in Vermont indicated that highway salting practices increased specific conductance, sodium, and chloride content of the soil solution, resulting in higher uptake and accumulation of these ions in damaged trees. During winter, sodium and chloride ions entered the soil and progressively penetrated and accumulated in deeper horizons with time. Deterioration of silver maples resulted from chloride toxicity and to some extent sodium rather than osmotic effects. Studies with grasses showed a close relationship between rates applied and amounts of sodium and chloride in tissues. Chloride accumulated several times higher than sodium. Kentucky 31 fescue maintained reasonable ground cover even at 4 to 6 tons of sodium chloride per acre. Potassium phosphate and sulfate in deicing salts tended to minimize salt injury to grasses.

SUPPORTED BY Virginia State Government

2.0409, ACID MINE POLLUTION
K.B. CUMMINGS, Virginia Polytechnic Institute, Agricultural Experiment Sta., *Blacksburg, Virginia* 24061 (VA-0303238)

OBJECTIVE: Abandoned strip mines in Smith County, Virginia have contributed heavy loads of silt to the streams which drain them. Forest Service projects to improve the affected zones have been carried out but the indirect abatement of stream pollution has not been documented. The purpose of this research is to itemize the damage that has been done to stream biota and habitat, to present evidence for stream recovery, and to indicate the relative role of harmful components in the silt on two drainage systems adjacent to the affected lands.

APPROACH: Two stations each for tributaries of Cripple Creek and South Fork Holston River will be studies. Four categories of tributary will be designated: control, completely reclaimed, partially reclaimed, and unreclaimed. Chemical, physical and biological properties of all streams will be compared and evaluated for degree of damage or recovery.

PROGRESS: The objectives of this proposed research are to monitor water quality in four tributaries which represent various stages of recovery from strip-mine pollution and to conduct studies on the chronic physiological action of mine effluent on fishes of these waters. The change in water quality following different stages of reclamation work on National Forest Lands have been used to measure the rate of stream recovery as well as to document the continuing damage caused by unreclaimed mines. The sublethal action of suspended matter and manganese metal upon the growth rate and condition index of two representative species, rainbow trout and white sucker, in this watershed are being evaluated.

2.0410, AN EVALUATION OF THE PRODUCTIVITY CHANGES ASSOCIATED WITH LIMING OF SHERWOOD LAKE, WEST VIRGINIA
K.B. CUMMINGS, Virginia Polytechnic Institute, School of Agriculture, *Blacksburg, Virginia* 24061

The increase of water hardness by artificial introduction of lime to Lake Sherwood has been studied over a period of four years. The objectives of the present study are: 1. To determine the pretreatment water quality, productivity, and harvest of Sherwood Lake. 2. To determine the effect of liming on water quality, productivity and harvest by periodic water checks, plankton and fish population sampling and creel surveys.

SUPPORTED BY Virginia State Government

2.0411, INVESTIGATION OF SURFACE FILMS - CHESAPEAKE BAY ENTRANCE
C.L. SMITH, Virginia Inst. of Marine Sci., *Gloucester Point, Virginia* 23062

This study involves determination of transport and fate of spilled oil in marine and estuarine waters. It includes the following primary tasks: 1) Document compositional changes in No.2, 4, and 6 oils spilled in the open ocean and in Chesapeake Bay by gas chromatography, infrared spectrophotometry, column chromatography and other techniques for oil analysis. Water and oil samples will be analyzed to investigate losses of volatile and water soluble components of the oils. 2) Determine the effect of weather and water currents on the movement, spreading, evaporation, and diffusion of these fuel oils in the open ocean and Chesapeake Bay.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0412, THE ROLE OF PAPER MILL ADDITIVES AS POTENTIAL STREAM POLLUTANTS
R.M. CHATTERS, Washington State University, School of Engineering, *Pullman, Washington* 99163 (AT(45-1)-2221)

During the course of producing paper, many chemical compounds are added to the paper process lines. These may serve the purpose of water repellency, high liquid absorbency, bleaching, chip digestion, filling, pigmenting, sizing, size precipitating, coloring, coating and run the gamut from simple natural substances to complex organic compounds.

Useful and necessary as these materials are to the paper industry, many of them are potentially harmful when introduced as effluents in public waterways. For example, bleaching compounds can increase the hardness of the receiving water; coloring materials can increase the B.O.D., impart color, some may be toxic thus upsetting natural purification of the streams, some may be carcinogenic while others impart taste and odors to the recipient waters; sizings may increase the B.O.D., interfere with reaeration,

or impart tastes and odors to the streams receiving them; some precipitating agents serve as nutrient media for algae and coatings may increase the turbidity of the waterways.

In the subject research, the principal aims are to determine how much additive is actually required by the fibers and how much of it leaves the paper mill as a potential pollutant or as an active primary pollutant. Neutron activation analysis techniques will serve as the main analytical tools in this research.

From these studies, then, it is hoped to provide information which will reduce the possibility of pollution from paper mills and at the same time reduce the paper industry's economic loss which results from unused additives leaving the production lines in the waste waters.

SUPPORTED BY U.S. Atomic Energy Commission

2.0413, OCCURRENCE OF PESTICIDES IN AQUATIC ENVIRONMENTS

E. HINDEN, Washington State University, School of Engineering, *Pullman, Washington* 99163

The method of transport to and the occurrence of pesticides in the aquatic environment is of extreme interest today. The increased use of pesticides for achieving higher agricultural and silvacultural productivity has allowed a greater amount of pesticides to enter into the aquatic environment. Though these amounts are generally in sublethal dosages, their presence constitutes a potential hazard. Certain pesticides can be concentrated in tissues of most organisms, thus entering in the food cycle of organisms in the aquatic habitat.

The purpose of this study is two fold. One purpose is to study the distribution of a chlorinated organic and organic phosphorus insecticide on an agricultural plot receiving insecticide application. A distribution budget will be made from analysis of soil, plant, and insecticide removal by irrigation runoff water and loss to the atmosphere taken throughout the growing season. Particular attention will be paid to that amount being carried off by the irrigation runoff water. During the second year insecticides will not be applied. A distribution budget will be made of the insecticides present on the plot. Emphasis will be placed on the insecticides leaching off the field in the irrigation runoff water.

The second purpose of the study is to determine the seasonal variation in the pesticide content of a dimictic and of a polymictic reservoir. Comparison will be made of the pesticide content of the water at specific depths, i.e. Epilimnion, Metalimnion and Hypolimnion. The surface inflows and outflows to the reservoirs will be sampled to better assess the pesticide variation. Samples of aquatic organisms, i.e., plankton, benthos, fish and snails, will be taken to determine the concentration of pesticides in organisms inhabiting the reservoir. Comparisons will be made of the pesticide content of those organisms feeding at specific depths.

2.0414, FRESHWATER ECOLOGY AT RATTLESNAKE SPRINGS

C.E. CUSHING, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

The stream at Rattlesnake Springs on the ALE Reserve offers research opportunities in freshwater biology, particularly for studies on the rate of elemental cycling. It is proposed first to examine the physical, chemical, and biological characteristics to provide basic knowledge of the major inventories of the ecosystem. Studies of mineral cycling, using short-lived radionuclides and pesticide cycling with tagged isotopes, will then be made.

RESULTS: Quantitative and qualitative studies of the aquatic flora and fauna on a seasonal basis was started. The seasonal variations in air and water temperature, flow rates, dissolved oxygen, alkalinity, dissolved minerals and nutrients, total dissolved solids, dissolved, total and particulate organics, and organic import and export were examined. Using the pH-CO2 relationships with the upstream-downstream method, estimates of primary production of the autotrophic populations are being made. Primary productivity of the emmergent macrophytes is being estimated by the harvest procedure.

2.0415, PRECIPITATION SCAVENGING

M.T. DANA, Battelle Memorial Institute, *Richland, Washington* 99352 (AT)

The objectives of the study are to determine the magnitudes, understand the mechanisms, and develop predictive capabilities to describe the removal by precipitation of pollutants from the atmosphere. Such removal is a major factor in the cleansing of the atmosphere, but may lead to health hazards at the earth's surface. For the scavenging of natural and anthropogenic particulates, it is important to categorize their size, electrical-charge, chemical behavior and other physical properties such as solubility and wettability; for gases, it is of importance to know and account for their solubility in water. Further, the hydrometeors must be classified as to size, shape, electrical charge, temperature and purity, and significant meteorological parameters must be measured and identified: ranging from those which influence the climatology of a region, such as orographic lift and proximity of precipitation modifiers, to microscale parameters such as turbulence, temperature and humidity. Three facets of the program are pursued simultaneously. The major effort involves field measurements of scavenging coefficients, precipitation characteristics and atmospheric parameters; a second involves controlled parametric and technical- development laboratory work; finally, the results are interpreted and analyses are performed.

Results: Washout experiments for rhodamine dye particles with mass median diameter between 1.5 and 9.5 microns were performed. Dry deposition was evaluated and comparable values of the deposition velocities were obtained for similar conditions. Measurements were made at the Olympic Peninsula field research site of rainfall intensity, raindrop size spectra, and electrical charge on individual raindrops. It was demonstrated that thermophoresis can dominate both diffusiophoresis and Brownian diffusion in the scavenging of submicron aerosol particles.

2.0416, COLUMBIA RIVER SEDIMENT STUDIES

J. NIELSEN, Battelle Memorial Institute, *Richland, Washington* 99352

PNL provides analytical services for the Columbia River and estuary studies being conducted by the USGS for the AEC, aids in the evaluation of the fate of the radionuclides, especially in the area of effect of retention by sediments, and conducts geochemical studies involving mechanisms of radioactivity uptake by the sediments.

SUPPORTED BY U.S. Atomic Energy Commission

2.0417, IN-CLOUD SCAVENGING

R.W. PERKINS, Battelle Memorial Institute, *Richland, Washington* 99352 (AT)

The study concentrates on certain aspects of precipitation scavenging namely, the cloud processes which are instrumental in transferring airborne contaminants into the precipitation elements and which transfer the contaminants to the ground. Three major aspects of the field-experimental approach are used. In one, the flux of radionucides carried by precipitation to the ground is measured and used to interpret the time scales for cloud development and for the in-cloud scavenging of naturally occurring aerosol particles. A second aspect is to make airborne releases of artificial tracers and subsequently detect the tracer both in the cloud and on the ground. The third aspect is to obtain concurrent meteorological measurements.

There are also three closely related aspects of the theoretical analysis. One concerns the analysis of microphysical processes within the cloud. At a larger scale, in order to quantify the global aspects of in-cloud scavenging, investigations are necessary to evaluate entrainment, turbulent diffusion and transport within a cloud, and synoptic scale motions. The third aspect is the numerical modeling of moisture-laden orographic flow, to predict meteorological variables within the cloud.

Results: Three coastal rainstorms were monitored to determine the flux of cosmogenic radionuclides carried to the ground by precipitation. The framework of a two-dimensional airflow model was developed and programmed for the 1108 computer. Theoretical analyses were made to interpret the in-cloud scavenging of particulates tagged with Na-24, and to identify the role of thermophoresis in in-cloud scavenging.

2.0418, PHYSICAL AND RADIOLOGICAL CHEMISTRY OF OCEAN SOLUTIONS
D.E. ROBERTSON, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

This study is designed to investigate the rates and mechanisms of the chemical and mixing processes in the ocean by use of the ocean's natural and artificial radionuclides or tracers and by application of the most advanced measurement techniques. Fallout radionuclides and neutron activation products, as well as their corresponding stable trace elements, are measured in seawater, marine organisms, and sediments to provide specific activities in various sectors of the marine environment. The ocean inventory of fallout radionuclides is determined by measuring the depth distribution over wide geographical areas. The physical and chemical forms of the radionuclides and trace elements (ionic, colloidal, chelate, particulate) are determined in an effort to describe the factors governing their concentrations and behavior in the ocean. Studies of the rates of vertical diffusion of surface waters across the established thermoclines are accomplished using the cosmic- ray-produced radionuclide Be-7 and the natural isotopes. The combined measurements will provide the necessary information to determine the rates at which the various elements and pollutants move through the marine food chain to man. Processes which lead to sedimentation will be clarified through measurement of the composition of sediments.

Results: The latitudinal influence on the deposition of cosmogenic Be-7 and fission products was measured in surface seawater samples. Vertical diffusion coefficients across the main thermocline in the open ocean between Hawaii and California ranged from 0.3 to 0.6 per square centimeter as determined from vertical concentration gradients of Be-7. The distribution of mercury in Atlantic Ocean water and its adjacent seas averaged 0.10 micro grain Hg/l, with a range from 0.06 to 0.19 micro grains/l. In oceanic waters, cobalt distributions are extremely variable, with the average concentrations in specific regions varying only two- to threefold.

2.0420, RATES AND MECHANISMS OF BIOGEOCHEMICAL CYCLING PROCESSES OF THE COLUMBIA RIVER
D.G. WATSON, Battelle Memorial Institute, *Richland, Washington* 99352 (AT(45-1)-1830)

A major goal of the work is an understanding of the functioning of the river as a dynamic ecosystem. The exchange of nutrients and other chemical substances between the several compartments of the ecosystem is of particular interest, and when the rates of exchange can be described in quantitative terms, extrapolation to other ecosystems becomes possible. The study involves measurement of the rates of exchange of selected chemical elements between the water, the various trophic levels, and the substrate of the Columbia River. Radionuclides from the Hanford production reactors selected for the most intense study initially are phosphorus-32, zinc-65, and chromium-51. Measurements of uptake and loss of the radionuclides will be made on organisms actually living in the river. In this way, both the rate of accumulation and the retention of the radioelements are determined. In order to obtain definitive resolution of the field picture, companion studies are carried out in laboratory facilities.

Results: Zinc-65 cycling by periphyton was investigated, including the effects of varying ambient concentrations and competing stable divalent cations upon uptake. For varying ambient concentratons, the uptake curves exhibited equilibrium conditions typical of a closed system. These curves were a reflection of the decreasing ambient concentration and did not represent true uptake equilibrium. Zn-65 cycling was studied in a water-periphyton-fish food web, using laboratory streams. In streams in which the water concentration of Zn- 65 differed by an order of magnitude, a 3- to 5-fold difference in Zn65 concentrations was measured in the periphyton, and a 1.5- to 3-fold difference in the fish.

2.0423, ANNUAL PHYTOPLANKTON PRODUCTION IN PUGET SOUND WATERS
G.C. ANDERSON, Univ. of Washington, Graduate School, *Seattle, Washington* 98105

Studies of phytoplankton production are being continued in Puget Sound. The investigation, since 1964, has provided quantitative information on annual phytoplankton production and mean standing crop in two areas of the Sound.

The research proposed herein is to elucidate the reasons for the very large blooms off Seattle when maximum values of 6-7 g C/square meter are photosynthesized per day. Weekly, daily and diurnal sampling will be carried out during periods of high phytoplankton production along with measurements of hydrographic conditions, light and nutrients. Particular attention will be given to the effect of stability, as affected by tides and winds, on the timing of phytoplankton blooms. Measurements will be made of the chemical composition of the crop as well as growth rates of dominant species.

Experimental work involving studies of phytoplankton blooms in enclosed columns of water in situ will be carried out. In this manner, the effects of advection will be eliminated. Culture studies will be conducted with some of the herbivorous copepods.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0424, STUDIES OF THE CONCENTRATIONS OF UNREPORTED LONG-LIVED RADIONUCLIDES IN BIOTA AND OCEAN SEDIMENTS AT BIKINI AND ENIWETOK ATOLLS
T.H. BEASLEY, Univ. of Washington, School of Fisheries, *Seattle, Washington* 98105 (AT(45-1)2225)

The occurrence of long-lived radionuclides produced by the testing of nuclear devices at Eniwstok and Bikini Atolls will be investigated. Knowledge of the presence or absence of these radionuclides is of importance for several reasons: 1) scientists of many disciplines currently use long-lived naturally occurring radionuclides for studying meteorological, oceanographic and geochronological processes. The production of these same radionuclides by weapons testing can seriously alter conclusions based on measured contractions that are assumed to be naturally derived; 2) the identification of radionuclides, previously unidentified as the product of nuclear devices, would be valuable to researchers concerned with the use of nuclear devices as a means of excavating canals and harbors; 3) the radiological environment which the beta of this area experience would be better defined. The techniques of multidimensional gamma-ray spectrometry will be used to identify and measure gamma-emmitting radionuclides, while low background beta counting and appropriate chemical techniques will be used to identify radionuclides whose only decay mode is beta partical emission.

SUPPORTED BY U.S. Atomic Energy Commission

2.0425, LEAD IN AQUATIC ENVIRONMENTS
T.M. BEASLEY, Univ. of Washington, School of Fisheries, *Seattle, Washington* 98105

The proposed research is aimed at characterizing the role played by biota in the distribution and cycling of lead in aquatic environments. Measurements of stable lead in fresh, estuarine and open ocean water and in selected organisms residing in these waters is underway. The research is designed to point out seasonal effects when lead concentrations in the waters are expected to vary greatly, i.e., periods of high rainfall for all waters and periods of coastal upwelling for marine waters. The proposed project period permits a recording of the lead pollution load of these environments as a result of increased industrialization and urbanization of the Puget sound and Pacific Northwest areas, thereby providing a baseline from which to observe the effectiveness of anti-pollution control measures aimed at reducing environmental levels of automobile exhaust, and other industrial wastes.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.0426, CONTROL OF PRODUCTIVITY AND POPULATION CHARACTERISTICS IN AQUATIC COMMUNITIES
W.T. EDMONDSON, Univ. of Washington, Graduate School, *Seattle, Washington* 98105 (AT(45-1))

The object is to analyze the mechanisms that control productivity and population characteristics in aquatic communities. The first stage consists of improving our knowledge of conditions as they exist in natural communities. The basic data consist of measurements of abundance, population structure, rate of activity and relevant environmental features. Much of the work is being carried out in lakes that have been altered in distinctive ways, e.g., the saline lakes in the lower Grand Coulee which have been diluted with fresh water from irrigation project. Other lakes have special features of interest, such as Hall Lake, which used to be meromictic and Mowich Lake, which has no planktonic crustaceans. These field experiments will be backed up by appropriate experiments in the laboratory, as suggested by correlations found in the field data. In addition, appropriate studies of sediment will be made to improve the degree to which the conditions in earlier times can be specified.

Results: A large body of information has already been obtained in previous investigations. Some has been published, and some is in advanced stages of preparation for publication. Much of the information concerns the way the fauna of the saline lakes has changed with more recent dilution, and measurements have been made of the osmotic pressure of blood of invertebrates held in different concentrations of the lake water. A detailed study of plankton productivity and population density has been made in Mowich Lake, and the consequences of the mixing of Hall Lake are being studied. Sediment cores have been taken from the lakes.

SUPPORTED BY U.S. Atomic Energy Commission

2.0427, RADIOCARBON IN THE SEA
A.W. FAIRHALL, Univ. of Washington, Graduate School, *Seattle, Washington* 98105 (AT(45-1))

Samples of sea water are collected and carbon dioxide is extracted onboard ship. Aliquots of the water are returned to the laboratory for total carbon dioxide analysis. The carbon dioxide samples are analyzed for their 14C content. In the upper few hundred meters of the sea, the 14C levels have been significantly perturbed by 14C from nuclear weapons testing in the atmosphere. The samples from the deep sea are presumably natural 14C from the atmosphere to the sea, and from the mixed layer of the sea into the deep sea. The rate of air-sea exchanges of carbon dioxide is expected to be proportional to the square of the average wind speed over the sea surface. In the deep sea, the levels of 14C and total carbon dioxide allow one to assess the rate of deep water advection from regions of deep water formation.

RESULTS: The levels of 14C in the atmosphere are currently about 50% above natural (pre-bomb) levels, and the mixed layer of the sea is about 30% above natural levels. The highest rate of transfer of 14C from the atmosphere to the sea is occurring at southern latitudes. There may be significant transfer of bomb 14C to the deep sea around the margins of Antarctica.

2.0429, NUISANCE ALGAL GROWTH RELATED TO ENVIRONMENTAL FACTORS
E.B. WELCH, Univ. of Washington, School of Engineering, *Seattle, Washington* 98105

A study of the relationship between pertinent environmental factors and the growth of nuisance algae in a highly eutrophic lake is proposed. The relative importance of light intensity, temperature, nitrate nitrogen and phosphate-phosphorus contents, degree of thermal stratification and detention time of the water in determining growth and species succession of the algae will be studied by field observation and statistical treatment of the data. As a potential method of algal control, the effect of nutrient dilution, with low-nutrient water, the presence of lake sediment, and water detention time on growth and species selection will be studied by in situ experiments in plastic bags. The usefulness of monitoring algal productivity in a lake by continuous measurements of dissolved oxygen in the surface water will be evaluated against the light-and dark-bottle method.

This study has particular relevance because of the future potential to evaluate flushing as a method of eutrophication control in Moses Lake.

2.0430, TOLERANCE AND CYTOLOGICAL RESPONSE OF ALGAE TO MINE WATER
H.D. BENNETT, West Va. University, Water Research Institute, *Morgantown, West Virginia* 26506

2. WATER QUALITY

Field and laboratory studies are to be conducted to gain further information on the tolerance of algae to mine water and the cytologic effects of mine water on the algae. This is to obtain information on what specific factors of mine water affect the occurrence, establishment, and abundance of algae in mine water, and to determine adaptations of algae that permit or do not permit tolerance to pollution.

Studies are to be made with collections from natural habitats, from field cultures, and cultures in the laboratory. The study will make use of algae known to be tolerant, algae not known to be tolerant, acid mine water, non-acid mine water, and non-polluted water. Physical and chemical factors of the water to be determined will include the major contaminants known to be characteristic of mine water. The cytological characteristics will be studied with the aid of the bright field, phase, and the electron microscope.

The laboratory and field data will be processed to permit drawing of conclusions, based on this and related work, that will help clarify algae-mine water relationships, and to point toward continuing research needed.

2.0431, GEOCHEMICAL BEHAVIOR OF IRON AND MANGANESE IN A RESERVOIR (LAKE LYNN, WEST VIRGINIA) FED BY STREAMS CONTAINING ACID MINE DRAINAGE

R.G. CORBETT, West Va. University, Water Research Institute, *Morgantown, West Virginia* 26506

Total Program - We proposed to study the geochemical behavior of iron and manganese in a dynamic system involving the impoundment of waters polluted by acid mine drainage. The natural model chosen is Lake Lynn, West Virginia, which has formed behind a dam constructed in 1929. The quality of water and abundance of fauna in the reservoir have deteriorated according to available data. An understanding of the behavior of iron and manganese in this environment should benefit many workers in water resources. The phases of research are ordered such that the project may progress as long as results appear fruitful.

Phase I - Areal Variation in Iron and Manganese Content of Sediments of Lake Lynn. From 150-200 samples of sediment from lake Lynn will be collected and analysed mechanically for particle size and spectrochemically for iron content and manganese content. Any variations present will suggest the course of future phases. Concurrently, the literature will be reviewed for information pertinent to the entire study.

Subsequent researches may involve mineral species in the sediments chemical stratification and seasonal variation thereof of iron and manganese in the impounded water and pore water of the sediment, co- precipitation of other elements with iron and manganese, and a chemical budget involving influx, precipitation, and escape at the reservoir outlet of iron and manganese.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0432, MICROBIOLOGY OF ACID DRAINAGE FROM COAL MINES

W.N. MILLAR, West Va. University, Graduate School, *Morgantown, West Virginia* 26506

In recent years considerable research effort has been directed towards studying the physiology of iron-oxidizing thiobacilli. These autotrophic bacteria (members of the Thiobacillus and Ferrobacillus genera) are responsible for producing much of the acidity found in coal mine drainage. However, little or no practical knowledge has yet been obtained which can be applied to control the activities of these organisms in their natural habitats. This problem of acid coal mine drainage will be investigated from an ecological point of view. The hypothesis adopted is that heterotrophic microbial populations are present in acid drainage and grow at the expense of organic compounds (e.g., pyruvic acid) released by the thiobacilli. If this hypothesis is correct, the removal of these toxic waste products by the heterotrophs must allow greater growth and acid production by the thiobacilli than if the waste products accumulated. Control of the heterotrophic populations in coal mine drainages might result in the partial control of the acid producing thiobacilli in such systems.

The initial objective of the research is to isolate indigenous heterotrophic bacterial and fungal populations from acid coal mine drainage, and to determine their ecological relationships with the iron- oxidizing thiobacilli.

Strains of 'Bdellovibrio bacteriovorus' will be examined for the biological control of the iron-oxidizing thiobacilli. The results from these studies will be used to evaluate 'Bdellovibrio' as an agent for the abatement or control of acid production in coal mines.

SUPPORTED BY U.S. National Science Foundation

2.0433, MINING OPERATIONS FOR THE REDUCTION OF HARMFUL DRAINAGE FROM UNDERGROUND COAL MINES

E.B. WILSON, West Va. University, School of Mines, *Morgantown, West Virginia* 26506

The work is designed to establish those technically and economically optimal underground coal mine operating and planning practices which are or which can be employed as means of preventing or substantially reducing the generation and efflux of harmful (high iron and/or high acid) drainage water. In addition to a 'state of the art' publication describing and analyzing published information, a thorough study of current mining practices will be accomplished. This study will seek to reveal what can be done during the mining process to prevent water pollution and will be conducted by on-site interviews with mine production and engineering personnel. Observation of these procedures and the collection of water samples for analysis will verify their effectiveness and utility. Conclusions will be based on combinations of procedures and will be applied with consideration for mining method and mining conditions. The project will be conducted from February 1970 to July 1972.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0434, ACID MINE DRAINAGE MICROBIOLOGICAL STUDIES

H.A. WILSON, West Va. University, Water Research Institute, *Morgantown, West Virginia* 26506

The proposed studies will be concerned with: 1. The isolation and identification of the heterotrophic acid tolerant bacteria in sewage polluted acid mine drainage streams. These isolates will be compared with those isolated in sewage polluted 'normal' (non-acid) streams; 2. the isolation of yeasts and true fungi from sewage polluted acid mine drainage streams. These also will be compared with isolates from non- acid streams; and to determine the role yeasts may play in sewage decomposition under the acid conditions; 3. to determine the amino acids and carbohydrates in sewage (by chromatography) and to compare their decomposition rates under 'normal' (non-acid) conditions with their decomposition rates in acid mine water environments.

Yeasts become the predominating microorganisms in sewage-acid mine water mixtures under laboratory conditions and these microorganisms also occur in streams with those characteristics. It is not known just what their role is. Two species of yeasts have been encountered in all of the work in our laboratories on studies of sewage decomposition in an acid mine water environment; however, little work was done to determine the role they played.

2.0435, EVALUATION OF WETLAND IMPOUNDMENTS ON STATE-OWNED WILDLIFE AREAS

A.F. LINDE, State Dept. of Nat. Resources, *Madison, Wisconsin* 53701

1. Provide a continuing record of changes occurring in submergent and emergent vegetation on study impoundments as a result of time and applied management techniques. 2. Attempt to relate water chemistry to impoundment productivity, applied management practices, impoundment aging, and determine desirable chemical ranges for wetlands in the various regions of the state. 3. Record the amount of sedimentation occurring as an impoundment ages and determine its relationship to impoundment productivity and the magnitude of its effects on decreasing

water depth. 4. Record wildlife use on each study area, for purposes of determining wildlife response to applied management, and to document the amount and type of public use on the area as it reflects recreational values. 5. Test new techniques and develop existing techniques on a variety of study areas where their application would have value.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0436, PLANT-AVAILABLE PHOSPHORUS STATUS OF LAKES
D.E. ARMSTRONG, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

The proposed research plan involves evaluation of the role of phosphorus in eutrophication through an understanding of the factors controlling the amount of phosphorus available to algae and higher plants in lake waters. The approach will be as follows: 1. Standardize methods for the fractionation and quantitative determination of the major forms of phosphorus in lakes, including soluble inorganic, soluble organic, microbial algal and higher plant and sediment phosphorus. Forms of organic phosphorus and the total organic and inorganic phosphorus in the seston and sediments will also be investigated. 2. Determination of the relative rates of fixation of plant-available phosphorus in lake waters by microorganisms, sediments and higher plants as affected by environmental conditions, employing P32-labeled phosphorus compounds. 3. Establish relationships between the forms and amounts of fixed phosphorus in lakes and the actual and potential amounts of phosphorus available for aquatic plant uptake.

Experiments will involve simulated lake environments in the laboratory and analyses of samples taken from lakes at different stages of eutrophication.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0437, ROLE OF PHOSPHORUS-SEDIMENT INTERACTIONS IN EUTROPHICATION
D.E. ARMSTRONG, Univ. of Wisconsin, Graduate School, *Madison, Wisconsin*

The purpose of this project is to determine the relationships between sediment properties and the rate of P uptake or release as a function of limnological conditions. Initial emphasis was placed on the nature and mode of retention of sediment phosphorus. Future investigations will emphasize the factors and mechanisms controlling P uptake and release.

Sediments of diverse properties have been investigated to determine the sediment properties and other factors controlling P uptake and release by sediments. Total P ranged from 560 to 7000 ppm; 30 to 90% of the total P was inorganic P. Inorganic P was mainly non-occluded, exchangeable and associated largely with amorphous Fe in both the non- calcareous and calcareous sediments. Methods for total organic P determination were evaluated; forms and mobility of organic P are under investigation. Retention of added inorganic P was generally greater for non-calcareous than for calcareous sediments and related to levels of native total and inorganic P in the sediments. Amorphous Fe played a major role in P retention. Future work will emphasize P desorption, exchangeability and biological availability. The project was initiated in September, 1968 and is expected to be completed in July, 1972.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0438, MERCURY TRANSFORMATIONS IN RIVER BOTTOM SEDIMENTS
G.M. BOUSH, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

The ultimate objectives are to obtain pure cultures of microorganisms capable of growth in environments high in divalent mercury ions; (b) determine the role of microorganisms in the transformations of mercury from inorganic to organic form; (c) determine the role of mercury tolerant microbes in the accumulations of mercury from contaminated effluent; (d) study the mechanism involved in the movement of mercury within aquatic food chains; and (e) attempt to clarify the mercury chemical form or forms present in various environments.

Efforts will be made to study the roles of microorganisms in affecting the fate of inorganic mercuric ion by using the aquatic microorganisms isolated from Wisconsin waters. The rates and conditions to form methyl mercuric compounds should be closely studied. The most important metabolic products from both phenyl mercury and from mercuric ions formed as a result of microbial action will be studied. Uptake, concentration, accumulation and transfer processes of such metabolic products by various ecosystems will be investigated. The water-sediment conditions which favor microbial activities to convert phenyl mercury and mercuric ions to more toxic methyl mercury and other forms which might facilitate biotransfer-accumulation will be investigated.

SUPPORTED BY Wisconsin State Government - Madison

2.0439, METABOLISM OF FIXED NITROGEN BY PLANTS AND BACTERIA
R.H. BURRIS, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

The Mo-Fe protein and the Fe protein which acting together fix nitrogen are being isolated and purified from Clostridium pasteurianum and Azotobacter vinelandii. The physical chemical properties of the proteins and the kinetics of their enzymatic activities are under study. The ferredoxin from Bacillus polymyxa has been shown to be functional in nitrogen fixation in this organism and the properties of the ferredoxin are being investigated. Flavoproteins and non-heme iron proteins have been isolated from A. vinelandii and the role of each in electron transport and nitorgen fixation is sought. The ferredoxins from blue- green algae are being compared with ferredoxins from other sources to determine how the blue-green algae fit the evolutionary pattern of this protein. Field experiments are being conducted to establish the role of the nitrogen fixing blue-green algae in eutrophication of fresh water lakes.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0440, DETECTION OF LIMITING AND SURPLUS NUTRIENTS IN ALGAE
G.P. FITZGERALD, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

Previous reports have described techniques developed for the detection of limiting or surplus phosphorus in algae. The present work involves the evaluation of a technique for determining if algae were limited by their nitrogen supply. It has been shown that labile carbohydrate reserves tend to build up in algae when they are deprived of sufficient nitrogen for normal growth. It is possible to detect these reserves considerably before the total nitrogen content of the algae starts to decrease. The development and loss of the reserve carbohydrate has been used to follow the development of nitrogen starvation and reversal of starvation by the addition of ammonia or nitrate nitrogen. The significance of these tests to algae in general and to the ecology of nitrogen nutrition in water pollution will be further evaluated.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0441, NUTRIENT SOURCES FOR ALGAE AND THEIR CONTROL
G.P. FITZGERALD, Univ. of Wisconsin, Graduate School, *Madison, Wisconsin*

In order to make logical decisions concerning the nutrients responsible for obnoxious growths of algae we must know the sources of available nutrients. This project has been designed to make use of techniques for the detection of limiting or surplus nutrients, to demonstrate the adaptations algae can make in order to utilize different forms of nutrients, such as polyphosphates, and provide short-term tests which can be conducted under controlled conditions to evaluate such conditions on the availability of certain nutrients. Through the use of these bioassay techniques for nutritional studies of problem-causing algae, it is proposed to study the sources of nutrients available to algae and to evaluate possible means of limiting these available sources.

Effect of Detergent Builder Replacements on Copper Toxicity - Preliminary tests of the effects of NTA, EDTA, HEDTA, and

HEIDA on the algicidal (Microcystis) and algistatic (Chlorella) properties of copper sulfate have indicated that the presence of these products will decrease the toxicity of copper applied to lakes for algae control. This subject will be further evaluated along with a complete literature review of algicide applications in general.

Field Test of the Availability of Phosphorus in Lakes of the Madison Area - By using the acetylene reduction method involving phosphorus limited nitrgen-fixing algae the availability of P will be followed in Madison Lakes at different depths in both the epilimnion and hypolimnion.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0442, THE TREATABILITY OF LEACHATE FROM SANITARY LANDFILLS

R.K. HAM, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

One outcome of the increasing awareness by the public in environmental concern is the attention being given to the contamination of ground and surface waters by leachate from sanitary lanfills. The primary objective of this study is to indicate the usefulness of several methods of leachate treatments by which such contamination may be reduced.

When available, it is likely that the most desirable means of leachate treatment will be simple discharge into a municipal sewer for treatment at the sewage treatment plant. The project includes a study of the implications of such a practice, including determination of the minimum amount of sewage necessary to dilute leachate to avoid disrupting activated sludge or trickling filter processes. In the absence of a sewer, a special treatment process must be used. Basic processes to be investigated for this purpose include lagoons, chemical precipitation, flocculation and sedimentation. Process efficiencies for leachate treatment, and critical characteristics of leachate which may indicate the effectiveness of each of these processes, will be determined for several process configurations.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0443, EXPERIMENTAL REVERSAL OF THE LAKE EUTROPHICATION PROCESS

A.D. HASLER, Univ. of Wisconsin, School of Letters, *Madison, Wisconsin* 53706

The proposed research program will attempt to evaluate the hypothesis that artificial acceleration of eutrophication (assuming a fixed, irreducible influx of nutrients) will ultimately result in a decrease in the rate of eutrophication and a temporary increase in production of food and other organic matter.

The majority of experimentation will be done IN SITU, using natural and artificial lake basins (Chippewa and Vilas Counties, Wis.). The acceleration of eutrophication at a predetermined, fixed level of nutrient influx, will be attempted by means of artificial lake circulation and artificial lake warming.

Biological indices of eutrophication, including photosynthetic rates, (14C method), diversity of bacteria and phytoplankton, and rates of zooplankton and fish production will be measured.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0444, A SYSTEMS ANALYSIS OF WATER AND NUTRIENT FLOWS IN THE LAKE WINGRA BASIN

D.D. HUFF, Univ. of Wisconsin, Water Resources Center, *Madison, Wisconsin*

The long-range goal of this interdisciplinary project is development of a capability for computer simulation of the cycling and distribution of eutrophic materials in the environment. The research approach consists of parallel development of nutrient transfer function models and a computer simulation model which combines mathematical representations of hydrologic processes and associated eutrophic- materials cycling.

The major anticipated result of the project will be the use of a simulation model to study probable changes in eutrophic states of lakes which may be attributed to human impact, and to develop methods for control. A second important result is the use of nutrient transfer function models as an aid in determining overall completeness and adequacy of the eutrophication research program.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0445, NITROGEN TRANSFORMATIONS IN LAKE SEDIMENTS

D.R. KEENEY, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

The overall objective of the investigation is to elucidate the nitrogen status and transformations in fresh water lake sediments as a means of evaluating the contribution of nitrogen to the relative state and rate of lake eutrophication. This objective is subdivided into the following specific objectives: 1. To determine the types and amounts of nitrogen present in sediment profiles of fresh water lakes as a function of the state of lake eutrophication. 2. To elucidate sediment properties and environmental factors controlling net nitrogen mineralization or immobilization in lake sediments.

The ultimate aims are (a) to provide an index of present and past fertility status of lakes by an examination of the nitrogen status of and transformations in sediments, and (b) to quantitatively define the nitrogen additions to and releases from sediments as a function of lake type, and nutrient input at different times of the year.

The project was initiated on September 1, 1968, and will be completed on June 30, 1973.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0446, MERCURY UPTAKE AND RELEASE BY BOTTOM SEDIMENTS

D.R. KEENEY, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

The ultimate objective is to evaluate the uptake and release of mercury by bottom sediments as related to (1) the influence of sediment and water properties; (2) the amounts and persistence of inorganic and organic mercury; and (3) the availability of mercury for biological uptake.

Detailed objectives are to determine the uptake and release of native and added HgO, Hg2 ion, MMC, DMM, PMA and PMH. Sorption- desorption isotherms of sediments from several Wisconsin rivers differing in chemical and physical properties will be obtained. The effect of water composition and redox status of the sediments on uptake and release of Hg compounds will be determined. The exchangeability of native and added Hg will be determined by isotopic (Hg^{203}) techniques.

The forms and distribution of Hg compounds in Hg-polluted and Hg- amended sediments and waters will be determined using the methods currently being developed and evaluated. Amended sediments will be incubated under oxygenated or anoxic conditions at varying temperatures to ascertain the effect of environmental conditions on the rate and extent of Hg transformations. Permanganate traps will be utilized to collect Hg volatilizing from the model systems.

SUPPORTED BY Wisconsin State Government - Madison

2.0447, ROLE OF SULFATE AND MANGANESE OXIDES ON THE RELEASE OF PHOSPHORUS FROM LAKE SEDIMENTS

G.F. LEE, Univ. of Wisconsin, Graduate School, *Madison, Wisconsin*

A project will be initiated on the role that sulfate and manganese oxides may have in the release of phosphorus from lake sediments. The primary approach will be to add known amounts of sulfate and MNO_2 to freshly collected lake sediments in laboratory leaching tests. The phosphorus concentrations will be monitored during the leaching tests over a period of several weeks to several months. If sulfate and MNO_2 cause an increase in phosphorus release under either aerobic or anaerobic conditions, studies will be conducted to determine the effect of these species concentrations of the kinetics of P release.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0448, SYSTEMS MODELING OF THE AQUEOUS ENVIRONMENTAL CHEMISTRY OF PHOSPHORUS AND NITROGEN IN LAKE MENDOTA
G.F. LEE, Univ. of Wisconsin, Graduate School, *Madison, Wisconsin*

Objective of this project is to develop a crude mathematical model that will demonstrate the various sources and sinks for nitrogen and phosphorus compounds in Lake Mendota, Madison, Wisconsin. The components of this model will include the amounts of nutrients transported from the watershed, the uptake and release of these nutrients or aquatic organisms within the lake and the lake sediments as well as the removal of these compounds via the outlet and other modes of transport such as insect larva, aquatic weed harvesting and fish removal. Particular attention will be directed toward determining the role of the thermocline in controlling the release of nutrients from the lake sediments during the summer periods of thermostratification. Total mass of N and P compounds present in the lake will be evaluated by periodic sampling of the water in determining the nitrate, ammonia and organic nitrogen, orthophosphate and total phosphorus. One of the primary objectives of this systems modeling project will be to evaluate the relative significance of the various components that influence the amount of nitrogen and phosphorus compounds available for aquatic plant growth within this lake. This type of information will be used to define those areas which need additional attention in order to develop or generalize and refine mathematical models for the aqueous environmental chemistry of nitrogen and phosphorus.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0449, EUTROPHICATION - N CYCLE - NITRIFICATION AND DENITRIFICATION
E. MCCOY, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

This study involves biological nitrification as contributor of nitrate (or ammonia and nitrite) to eutrophication of lakes and streams, the identification of the groups of nitrifiers involved and of their site of activity. Because denitrification may reverse the process it is also being studied as to the bacteria concerned and their potential activity.

Sites representing open water, underlying mud and beach areas on 5 lakes and 4 streams in the Madison area were surveyed in summer 1969 and are now being monitored in spring, summer, and fall 1970. Water samples are generally negative, occasional water samples from bays and backwater inlets are positive - less than 3 ppm as nitrate. Shore samples, particularly under decaying algae or 'Lemna', are strongly positive at 15 ppm to as much as 180 ppm in late summer. Ammonia is always near algal masses, highest value being over 600 ppm. Nitrite is occasionally found without nitrate. Denitrifying bacteria in open water of weedy bays may reach 10,000/ml.

The field study will continue through summer and fall of 1970 and will be followed by laboratory study of the bacteria during academic year 1970-71.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0450, UNSTEADY FLOW OF GROUNDWATER--DISPERSION AND SALT WATER INTRUSION IN NON-HOMOGENEOUS MEDIA
P.L. MONKMEYER, Univ. of Wisconsin, School of Engineering, *Madison, Wisconsin*

In the study of dispersion in non-homogeneous porous media, a general solution for the distribution of a contaminant in one dimensional flow through a layered or continuously graded media has been obtained. For two and three layer systems, the solution has compared very well with experimental data. The solution can be adapted to non- uniform flows. Currently, additional experiments are being carried out to verify the theoretical model.

Subsequently, the work will be extended to salt water intrusion in non-homogeneous, coastal aquifers. This investigation will involve analytical and experimental models of the instantaneous and quasi steady salinity and velocity distributions in confined, layered aquifers. The influences of disperson and pumping and recharging wells will be considered.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0451, EUTROPHICATION OF NATURAL WATERS
G.A. ROHLICH, Univ. of Wisconsin, Water Resources Center, *Madison, Wisconsin*

The research objectives of this multidisciplinary program are to make indepth studies on the eutrophication of natural waters. Among some of the specific objectives are: 1. Determine the cause-and-effect relationship between natural aging of lakes and inadvertent enrichment which leads to short-term changes in water quality in terms of physicochemical and biological factors. 2. Develop methods of forecasting variations in quality of lake waters by the examination of early trends. 3. Contrive methods of management to control optimum quality of lake waters for municipal, industrial, agricultural, and recreational uses and to arrest or reverse eutrophication trends. 4. Examine the interrelationships among several variables pertaining to the process of eutrophication and exclude those which prove to be of doubtful value for continuing interdisciplinary comprehensive studies. 5. Establish a research program that will generate the kinds and amounts of data needed for systems analysis of the total problem by a competent environmental scientist.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0452, MULTIPLICATION OF CLOSTRIDIUM BOTULINUM TYPE E IN THE GREAT LAKES
H. SUGIYAMA, Univ. of Wisconsin, Graduate School, *Madison, Wisconsin*

Clostridium botulinum type E is present in all four of the Great Lakes studied, but the source of the organism is not fully understood. Contrary to the explanation advanced for foci of concentration of the organism in marine areas, our work suggests type E to be actively multiplying in the lakes.

The proposed research will emphasize Green Bay, which has an exceptionally high level of type E. 1. Seasonal fluctuations in the type E populations at selected locations will be sought to establish cyclic changes in numbers. 2. The depth at which maximum counts of type E exist will be determined with cores of bottom deposits. 3. Combination of vegetation and bottom deposits subjected to alternate freezing and thawing (presumably equivalent to wintering in nature) may support type E growth. 4. Possible relationship between the pollution of the lower Fox River and the frequent samples giving negative control cultures will be studied. 5. Attempts will be made to develop an agar medium on which toxin-producing type E colonies can be readily distinguished.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0453, ECOLOGY OF CLOSTRIDIUM BOTULINUM TYPE E IN GREEN BAY
H. SUGIYAMA, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

Multiplication of Clostridium botulinum type E in Green Bay may have a seasonal basis. Attempts will be made to see if bottom deposits collected at several locations at frequent intervals will again show a high type E count in the spring followed by decreasing numbers during the summer and fall. Tests will be made to determine if type E will multiply in environmental samples which are repeatedly frozen and thawed in the laboratory.

Studies will be continued on the factors in certain environmental samples which inhibit the growth of type E. Differentiation of toxigenic type E colonies from non-toxigenic 'E-likes' will be attempted. The protoplasts and L-forms of C. botulinum are being studied. Possible multiplication and toxin formation of C. botulinum in vivo will be tested.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S

2.0454, NUTRIENT ENRICHMENT OF RUN-OFF WATERS BY SOILS. ENRICHMENT POTENTIAL OF URBAN SOILS IN THE CITY OF MADISON
J.K. SYERS, Univ. of Wisconsin, School of Agriculture, *Madison, Wisconsin*

The overall research objective is to evaluate criteria and develop tests for assessing the potential of soils for nutrient enrichment of run-off waters. In phase I, the phosphorus enrichment potential of urban soils in the city of Madison will be investigated. The approach will be as follows: 1. Determine the forms and amounts of inorganic and organic P in selected urban soils in the city of Madison. Soils from existing and future land development sites of high potential erodibility will be emphasized. 2. Determine the release and uptake or organic and inorganic P by the above soils as related to soil properties and run-off conditions. 3. Establish routine tests for predicting the potential of the soils for P-enrichment of run-off waters.

Experiments will involve simulated run-off, stream and lake environments in the laboratory. Extensive use will be made of P32 labeled compounds to evaluate the exchange-ability of adsorbed native and applied inorganic P and biological immobilization and release of P.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0455, EUTROPHIC EVALUATION OF A SMALL MULTI-LAND USE WATERSHED
A.E. ZANONI, Marquette University, School of Engineering, *Milwaukee, Wisconsin* 53233

The proposed project involves the determination of the quantities of nitrogen and phosphorus which originate from various land use activities in a small river watershed tributary to Lake Michigan in the Milwaukee metropolitan area. The watershed in question is the Menomenee River watershed which includes agricultural, residential, industrial, commercial, park and recreation, woodlands and wetlands, and governmental-institutional land uses, and yet encompasses a drainage area of only 135 square miles. Based on the results of preliminary surveys, sampling locations will be located at critical points along the river for discharge measurements and nitrogen and phosphorus analyses. These data will then be used to estimate the nutrient quantities from the various sources in the watershed. The data will also be correlated with hydrological and climatological data to establish the manner in which these watershed factors might influence nutrient quantities from the various sources.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0456, GROUND WATER POLLUTION FROM SANITARY LANDFILLS AND REFUSE DUMP GROUNDS - A CRITICAL LITURATURE REVIEW
A.E. ZANONI, Marquette University, School of Engineering, *Milwaukee, Wisconsin* 53233

The main objective of this study is to review the technical literature and research reports dealing with ground water pollution potential originating from the leachates of sanitary landfills and refuse dump grounds. The intention of this literature review is to determine the seriousness of this problem and on the basis of what is known, make specific recommendations to the Wisconsin Department of Natural Resources regarding the future selection and operation of disposal sites. Also it is anticipated that the review will suggest research programs to obtain needed information in this area.

In addition to technical journals and research reports, a survey will be conducted of the practice employed in this regard in some twenty states in the country. This survey will establish if any research has been done in this area, what regulations are in force regarding the selection and operation of refuse disposal sites, and if any new rules and regulations are being contemplated in the future.

SUPPORTED BY Wisconsin State Government - Madison

2.0457, WISCONSIN RIVER ICE STUDIES
N.P. LASCA, Univ. of Wisconsin, Graduate School, *Milwaukee, Wisconsin*

The objects of this project are: 1.) To determine the effect of river ice on channel development and erosion, 2.) To determine the relationship of pollutants to ice in rivers, 3.) To evaluate ice crystal growth and deformation under progressive stress occurring in ice piling against obstructions.

SUPPORTED BY U.S. National Science Foundation

2.0458, SEDIMENTARY FACIES IN LAKE BUTTE DES MORTS, WISCONSIN
J.W. MCKEE, Univ. of Wisconsin, Graduate School, *Oshkosh, Wisconsin* 54902

Lake Butte des Morts is a shallow, highly eutrophic lake which is undergoing rapid changes--some natural, some caused by man. Because of the importance of this and adjoining lakes to the large number of people who live nearby, management programs are desirable. But many of these should not be attempted until a greater understanding of physical processes in this lake is attained.

Toward this end a series of studies is being planned. This study (the first of the series) will result in a description of the present distribution of sediment types in Lake Butte des Morts. Samples will be taken from short cores, then subjected to standard laboratory procedures for determination of composition and of grain size mineral sediments. Isopleth maps will be constructed to show: 1. Proportion of organic matter or of mineral matter. 2. Mean grain size of sands. 3. Sorting.

A bathymetric chart will be constructed for comparison with previous data in order that the filling rate may be estimated.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0459, EFFECTS OF SOUTH SHORE DRAINAGE BASINS AND CLAY EROSION ON THE PHYSICAL AND CHEMICAL LIMNOLOGY OF WESTERN LAKE SUPERIOR.
D.A. BAHNICK, Univ. of Wisconsin, School of Letters, *Superior, Wisconsin* 54880

This project involves a geological and chemical investigation of a sector along the south shore of western Lake Superior. The study area includes portions of Lake Superior which are influenced by stream discharge and erosion of Pleistocene red clay. Water samples will be analyzed for phosphate, nitrate, copper, and conductivity. Bottom sediments will be analyzed for the distribution of particle size. Water samples will be collected in the littorial zone under both turbid and non-turbid water conditions (Turbid conditions indicating the presence of significant amounts of suspended solids).

The data will be analyzed for the effect of river discharge and red clay erosion on water quality. Statistical analyses of sediment samples will be contoured to determine stratigraphic facies relationships of recent lake bottom sedimentation.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0460, PHYSICO-CHEMICAL PROCESSES AND IONIC STATES OF MICROCONSTITUENTS IN SEA WATER AND THEIR RELATION TO RADIOECOLOGY OF NORTH ADRIATIC
M. BRANICA, Inst. Rudjer Boskovic, *Zagreb, Yugoslavia*

During the next period the problems will be devoted to the further development of new analytical procedures for the determination of the ionic states of some microconstituents as well as to their physico- chemical characterization in sea water, biota and sediments.

The research effort will be partly centered on the investigation of Kinetics and equilibria between various (ionic, complexed and particulated) species, present in the sea environment, as well as the exchange reaction with the added radionuclides in sea water.

Influence of different conditions in the sea environment on the charge of surfaces of abiotic particles will be also studied.

Techniques used will be mostly various polarographic techniques, electromigration methods and radiometric analysis.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

B. POLLUTION IDENTIFICATION

Measurement, Monitoring, Bioassay, Bioindicators, and Instrumentation. Includes Ecological Baseline Studies, Prediction and Forecasting of Water Pollution Potential.

2.0461, STUDIES ON THE INTERACTIONS OF BACTERIA AND NEMATODES

G.R. WILT, Auburn University, School of Veterinary Medicine, *Auburn, Alabama* 36830

Investigations conducted at Auburn University under OWRR Project A- 006-ALA have resulted in a better understanding of the interactions of aquatic nematodes.

The proposed research will extend from current knowledge with the following objectives: 1) Determine if certain water resources with their indigenous bacterial flora may serve to maintain and increase populations of nematodes known to be important to the welfare of man. 2) Determine what effect bacterial-feeding nematodes have on the bacteriological stabilization of organic matter. 3) Determine further the significance of virus-bacteria-nematode associations. 4) conduct studies on the occurrence and nature of nematocidal activity of aquatic bacteria. 5) Investigate the feasibility of using certain nematodes as rapid and specific indicators of pollution.

This proposed research will not be directed toward public health aspects, but rather towards a much broader base.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0462, AREA DESCRIPTIONS OF ALABAMA'S ESTUARIES

J.H. CRANCE, State Seafoods Division, *Dauphin Island, Alabama* 37528

Objectives: 1. To determine the physical characteristics of the estuarine areas of Alabama including the location, boundaries, acreage, depth, volume, predominant types of vegetation, discharge of streams, principal hydrological properties, special benthic features, human population, major economic features and discharge of effluents into each estuary. To publish an atlas of results.

Procedures: Existing reports, maps and other data of various agencies will be reviewed and analyzed and pertinent information will be compiled. Data not available will be obtained by field surveys. An atlas of the physical characteristics of Alabama's estuaries will be prepared in accordance with procedures adopted by the Technical Coordinating Committee of the Gulf States Marine Fisheries Commission.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.0463, VIROLOGICAL METHODS RESEARCH IN WATERS

W.F. HILL, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Dauphin Island, Alabama* 36528

This project is concerned with developing and evaluating the systems requirements for isolating virus from large quantities of virus- contaminated water. This includes, but is not limited to, waters used for drinking, recreation, reclamation, and food production. The major problem reduces to the inadequacy of available methodology to sample, isolate, and concentrate viruses occurring at low multiplicity levels in waters. Methods providing for at least a 1,000-fold concentration of virus are needed at the outset to satisfy a reasonable sensitivity level. At the outset, a sequential methods approach will be implemented. This approach will encompass the adaptation of membrane filtration to sampling and recovery of viruses from large volumes of environmental waters. Concentration of low multiplicities of recovered virus from eluates will involve evaluation of a number of procedures such as hydroextraction, polyelectrolyte and/or aluminum salt flocculation, and ultracentrifugation. Initially, the sequential methods technic will be applied to estuarine waters under laboratory conditions using a 'model' (poliovirus 1) enteric virus. This project was started in July 1969 and is continuing.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0464, BACTERIAL SURVEY OF MARINE BOTTOM SILT

B.E. HUNTLEY, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Dauphin Island, Alabama* 36528

Objectives of the project are to determine if the environmental conditions in the marine silt of Mobile Bay are conducive to bacterial growth with emphasis on the coliform indicator group of organisms. Information obtained from the study will be used to evaluate the validity of current standards which use the coliform bacterial group as reference for fecal pollution. Bottom 'silt' will be collected from selected sampling sites for (1) use in culture media at the laboratory to determine if it will support bacterial growth and (2) will be analyzed for its bacterial content. Sampling sites have been established in (1) areas permanently closed to the harvesting of shellfish because of pollution and (2) areas subject to seasonal closure during periods of increased river flow into the Bay. Physical parameters of the bay water and 'silt' at the sites are being monitored to determine if seasonal variations in the environment are a factor affecting bacterial growth. The project started in August 1969 and is continuing.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0465, CHEMICAL INDICATORS FOR FECAL POLLUTION

F.C. KOPFLER, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Dauphin Island, Alabama* 36528

The objective of this project is to evaluate the feasibility of using the end products of human and animal metabolism found in feces as chemical indicators of pollution. The ultimate goal is that the detection of certain metabolites will permit recognition of fecal pollution when enumeration of fecal indicator bacteria cannot be relied upon to do so.

This year the evaluation of coprostanol will be continued. Water from various sources will be examined for lipids which may interfere with the determination of coprostanol; clean-up techniques for these extracts will be refined or devised if necessary. The persistence of coprostanol in water under selected conditions will be investigated. The concentration of coprostanol will be compared with levels of indicator bacteria in sewage and selected natural waters.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0466, CHEMICAL POLLUTANTS IN THE ESTUARINE ENVIRONMENT

F.C. KOPFLER, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Dauphin Island, Alabama* 36528

The objectives of the project are (1) to determine the identity of organic pollutants in raw and finished waters; (2) to develop or refine methods of analysis for chemical pollutants; (3) to determine the significance of inorganic, natural or synthetic organic chemicals in various waters and (4) to determine the relationship of chemical pollutant concentrations in shellfish to the chemical state and amount of the substance present in the environment.

This year the accumulation rate and total accumulation of mercury by groups of oysters each exposed to a different chemical form of mercury in a flow-through aquarium will be investigated. Initially inorganic mercury, methyl mercuric chloride and phenyl mercuric acetate will be used.

The relationship between the elevated zinc burden in oysters and the apparently normal concentration of zinc in the overlying water at a particular location in Mobile Bay will be studied.

Silica-gel and flurosil column chromatographic clean-up techniques for pesticide extracts of water will be evaluated and compared as time permits.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0467, VIROLOGICAL METHODS RESEARCH IN WATERS
W.F. HILL, U.S. Environ. Protection Agcy., Gulf Coast Water Hygiene Lab., *Dauphin Island, Alabama* 36528

This project is concerned with developing and evaluating the systems requirements for isolating virus from large quantities of virus-contaminated water. The major problem reduces to the inadequacy of available methodology to concentrate and recover viruses occurring at low-multiplicity levels in waters used for drinking, recreation, reclamation, and food production. Methods providing for at least a 1,000-fold concentration and 50 to 100 percent recovery of virus are needed to satisfy a reasonable sensitivity and efficiency level. At the outset, a sequential methods approach was implemented. This approach encompasses the adaptation of the membrane-adsorption technique as the primary procedure for concentrating and recovering viruses from large-volumes (100-gallon quantities) of surface waters and finished water. Further concentration of low-multiplicities of recovered virus from filter eluates will involve evaluation of a number of secondary procedures such as two-phase separation, polyelectrolyte-adsorption, and continuous-flow zonal ultracentrifugation, to name a few. The sequential methods approach will continue to be applied to estuarine waters and tap water under laboratory-controlled conditions using a 'model' enteric virus (poliovirus type 1, LSc2ab). By combining the membrane-adsorption technique with aqueous polymer two-phase separation, volume reductions of 126,000 to 1 have been observed with up to 67% of the input-virus being recovered. The prototype-system has shown a capability for detecting virus occurring at multiplicities as low as 1 to 2 PFU per 5 gal from both fresh and estuarine waters.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0468, BIOLOGICAL PROPERTIES OF SEWAGE LAGOONS AT TUSKEGEE, ALABAMA
K.S. CHAHAL, Tuskegee Institute, School of Agriculture, *Tuskegee Institute, Alabama* 36088

This study will determine the efficiency of sewage lagoons and the effect of microorganisms and their byproducts on the quality of water in receiving streams. Samples of raw sewage and lagoon effluent will be analyzed for total solids, BOD, dehydrogenase activity, total microbial count, and relative proportions of different kinds of microorganisms during different seasons of the year. Microbial byproducts will be extracted from cultures of microorganisms isolated from samples. The biological activity of the byproducts will be tested using mammalian tissue culture technique. Parameters for bioassey will be cytochemical changes, synthesis of protein and nucleic acids, and total cell count. Identification of compounds will be by IR and UV spectrophotometry, gas, paper, and thin layer chromatographic methods.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0469, AQUATIC-BIOTIC COMMUNITY STRUCTURE AS AN INDICATOR OF POLLUTION
D.T. ROGERS, Univ. of Alabama, School of Arts, *University, Alabama* 35486

The species diversity of benthic macroinvertebrate communities will be investigated in several small streams which are affected by strip mine drainage. Iron, silica, copper and pH will be measured in the water from which the invertebrate samples are taken. A statistical analysis will be used to determine which of the water quality criteria have the greatest affect on the macroinvertebrate community structure as described by the formula d equals minue E p sub i log sub 2 p sub i where p sub i is the ratio of the individuals in species 'i' to the total individuals in the community. This study will cover a twelve month cycle.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0470, BASELINE WATER QUALITY STUDY OF THE ALASKAN ARCTIC ESTUARINE ENVIRONMENT
V. ALEXANDER, Univ. of Alaska, Inst. of Marine Sciences, *College, Alaska* 99735

The almost unknown environments of the shallow estuaries and barrier island complexes, the tundra lakes, and the rivers and streams of the Alaskan Arctic are suddenly being stressed by the influx of thousands of people engaged in construction, drilling, transportation, and exploration in support of the vast new oil strikes. The impact of this activity on the arctic aquatic ecosystems cannot be assessed without a basic knowledge of the existing virgin environment. It is therefore proposed that a year-round, baseline study of the water quality parameters and biota in the shallow arctic estuaries, lakes, rivers, and streams be undertaken immediately.

Specific tasks to be accomplished will involve detailed work in the Colville River area and comparative work all along the Alaskan arctic coast with special interest to be given to areas where immediate pollution problems exist. The detailed work will involve the physical circulation and flushing in the shallow arctic estuaries, the nature and movements of sediments, the ice movements in the estuaries and rivers with an eye to the effect of ice on the transport of pollutants, the chemistry and biology of primary productivity, and a survey of the biota of the fresh marine aquatic environments of the Alaskan Arctic.

This project will be part of a logistically combined, well planned coherent effort with the University of Alaska's Sea Grant effort in the Alaskan Arctic. 1 May 1970 is the starting date of the project and it is expected to run through 30 April 1971.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0471, ORGANIC COMPOUNDS IN ALASKA PERMAFROST GROUNDWATER
N.J. BIRKHOLZ, Univ. of Alaska, Inst. of Water Resources, *College, Alaska* 99735

Detection and identification of trace organic compounds in well waters associated with the interior Alaska permafrost regime are being studied using gas and thin layer chromatography and spectra. Surface waters and soil samples are being similarly investigated to the extent that they can clarify the origin of organics at deeper levels. Changes in trace organics will be studied during development of a well.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0472, THE LIMNOLOGY OF TWO DISSIMILAR SUB-ARCTIC STREAMS AND IMPLICATIONS OF RESOURCE DEVELOPMENTS
D. NYQUIST, Univ. of Alaska, Inst. of Water Resources, *College, Alaska* 99735

Many Alaskan rivers and streams are fed by surface and runoff carrying large quantities of suspended sediments, cold water tempratures, and, in many cases, significant ice cover. The river and stream to be studied in this project, Chatanika and Goldstream, not only have the above characteristics, but in addition, associated within the area, is one of the main population centers of Alaska.

The Institute of Water Resources has a basic need for the development of baseline data on a comparatively unpolluted stream system in order that it fulfill its studies of providing adequate advice in water resource management for large areas in the arctic and sub-arctic of Alaska with respect to their development by man.

The objectives of this project will be to: 1. Establish a record of the current flora and fauna before changes due to development by man can occur. 2. Compile a qualitative and quantitative standard against which future populations can be compared. 3. Assess the source and the amount of present nutrients which are being contributed to the streams. 4. To investigate the effect the present addition of nutrients is having on the community productivity.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0473, NAVY ENVIRONMENTS - ARCTIC SEA ICE ORGANISMS
R.A. HORNER, Univ. of Alaska, Institute of Marine Sciences, *Douglas, Alaska* 99824 (N00014-67-A-0317-0003)

Technical Objective: This work relates to improvement of Navy capabilities in marine vehicle and system operation in the arctic. Enhanced performance of surface and subsurface vehicles, systems and weapons will accrue through better understanding of the Navy environment in relation to the quantity, distribution and acoustic, optical, or fouling affects of marine biological populations. In addition, information relative to ecology, pollution, and environmental control of the arctic marine environment will be obtained.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.0474, THE QUALITY OF ARIZONA WATERS WITH PARTICULAR REFERENCE TO FLUORIDES
W.H. FULLER, Univ. of Arizona, School of Agriculture, *Tucson, Arizona* 85721

Work on this project to date has consisted of compiling analyses of waters from the Tanque Verde area, east of Tucson. The analyses are arranged according to the legal description of each well included in this study.

Wells in Township 13 S, Ranges 15 and 16 E; Township 14 S, Ranges 15 and 16, and 17 E; Township 15 S, Ranges 15, 16, and 17 E.

Work on this project has not proceeded to the point where conclusions may be drawn or the results plotted on a map.

SUPPORTED BY University of Arizona

2.0475, RADIOCARBON AS A TRACER IN GROUND WATER PROBLEMS
A. LONG, Univ. of Arizona, Graduate School, *Tucson, Arizona* 85721

The radiocarbon content of ground and surface waters is being used as a tracer to study surface and ground water movement. The data are being related to such ground water problems as the rate of laminar flow through aquifers, their permeability, the source, time and rate of charge, radioactive contamination in water supplies, and the waste disposal problem.

The increase in the carbon-14 content of the atmosphere, biosphere and hydrosphere due to nuclear technology is also being monitored.

2.0477, MATHEMATICAL MODEL OF MICRONUTRIENTS AND BIOLOGICAL PATTERNS IN LAKE MEAD
H.K. QASHU, Univ. of Arizona, Water Resources Research Ctr., *Tucson, Arizona* 85721

Progressive increases in concentration of dissolved solids in the Colorado River water from Lake Powell to Imperial Dam seem to alter plankton dynamics and biological productivity of the river. Also, changes in biological productivity and micronutrients concentrations occur within the same reservoir. Development of a digital simulation model to predict micronutrients concentrations and biological productivity is necessary for diagnosing changes in plankton.

The objectives of the study are: (1) to determine trace metal balance at different locations in Lake Mead, (2) to measure biological productivity and conduct plankton population counts at each sampling location, (3) to derive functions relating biological productivity to trace metal concentrations, suspended sediments and some physical variables (temperature, light, solar radiation), and (4) to develop a mathematical model for predicting spatial and temporal changes in biological productivity, plankton dynamics and trace elements concentrations.

Relationships of biological variables (phytoplankton, zooplankton, and biological productivity) to the chemical and physical variables of the aquatic system will be derived using statistical procedures and time series analysis methods. A digital simulation model will be developed with capabilities which allow coupling to a salinity model for the river and reservoir system(s).

2.0478, A CONTINUOUS COAGULATION EFFICIENCY MONITOR FOR WATER AND WASTE SYSTEMS
G. BROWER, Univ. of Arkansas, Water Resources Research Ctr., *Fayetteville, Arkansas* 72701

Coagulation of water and waste is very important to water resources. The mechanism of coagulation is one of the primary means of water purification. There is a need for an instrument that would check a water or waste system and determine the optimum coagulant dosage to be added. Currently, no such instrument exists. This proposal outlines the development of an instrument that the water or waste may be placed in and the optimum coagulant dosage will be read out. The instrument will be proven under actual field conditions. Cost economics of the instrument, savings in materials, and increased water quality will be determined.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0479, A EUTROPHICATION MODEL OF THE WHITE RIVER BASIN ABOVE BEAVER RESERVOIR IN NORTHWEST ARKANSAS
R.A. GEARHEART, Univ. of Arkansas, Water Resources Research Ctr., *Fayetteville, Arkansas* 72701

This research will attempt to evaluate the various nutrient contributors to a reservoir in Northwest Arkansas, namely Beaver Reservoir. The purpose is to predict by use of a mathematical model the rate at which this relatively new reservoir will accumulate nutrients. This involves identifying and quantifying on a time-series basis those elements which accelerate eutrophication. The three most common elements known to affect aquatic productivity are carbon, nitrogen, and phosphorus. The major contributors of nutrients to receiving waters are: sewage effluent, urban runoff, agriculture practices, and recreational activities, - all of which can be isolated and monitored in this particular system.

The implementation of this research is as follows: 1) A preliminary examination and isolation of nutrients contributors. 2) Location of sample points based on preliminary examination. 3) Establishment of a sampling schedule which will yield the greatest information with the smallest error. 4) Collect necessary data for input into mathematical model. 5) Construct and computerize mathematical model with acquired data. 6) Predict further eutrophication rates with mathematical model.

2.0480, MINERAL ANALYSIS OF WATER
W.E. SABBE, Univ. of Arkansas, Agricultural Experiment Sta., *Fayetteville, Arkansas* 72701 (ARK00536)

OBJECTIVE: Provide a facility whereby rural residents of Arkansas can have their domestic waters analyzed for those minerals which tend to render it objectional for general

household use. Accumulate and disseminate data on the chemical content of Arkansas' ground waters.

APPROACH: Water samples forwarded to the laboratory via the County agent will be analyzed for hardness, pH, total dissolved salts and iron. The report, which is returned to the farmer via the County Agent, will describe the water quality and recommend type of water conditioning equipment needed (if any) to improve water quality.

PROGRESS: For the 1969 calendar year 1637 domestic and 145 irrigation water samples were analyzed for various mineral content. This compares with 878 and 171 for 1968 and 809 and 118 for 1967. An additional 203 special tests were performed. Manganese in domestic water was determined on samples submitted in 1968 and 1969. Forty-eight percent of the samples had Mn in excess of the maximum level established for Public Health Standards while thirty-four percent contain Mn levels above which domestic users complain about difficulties in washing and cooking. Therefore the determination of Mn will be a routine test beginning in 1970 and domestic users will receive the necessary recommendations for its removal from their water.

SUPPORTED BY Arkansas State Government

2.0481, DIGITAL SYSTEMS FOR ON-SITE DATA COLLECTION FOR WATER QUALITY ANALYSIS
M.K. TESTERMAN, Univ. of Arkansas, Graduate School, *Little Rock, Arkansas* 72005

The proposed work is concerned with the development of an electronic digital system for on-site data collection in water resources research and control programs. System design objectives include (1) data recordings directly readable by computer input devices, (2) a selectable number of measurement channels within a design maximum, (3) system operation either independent or in synchronism with other equipment of the same type, (4) provisions for interfacing with telemetry packages or data modems for transmission over communication networks (e.g. Bell System Dataphone).

The work would involve establishing data acquisition requirements and sources of error, data system requirements and performance constraints, and system equipment design.

2.0486, TASTES AND ODORS IN WATER SUPPLIES
D.I. JENKINS, Univ. of California, School of Engineering, *Berkeley, California* 94720

The proposed research is a continuation and broadening of current work concerned with the identification and resolution of the source and nature of odorous compounds in natural waters. Emphasis is on the study of aquatic organisms as one of the major contributors to the problem of taste and odor in waters.

Conventionally the major odor categories include medicinal (phenolic-type compounds), fishy (nitrogen and sulfur-containing compounds), sulfidal and terpenoidal. Papers have been or are in the process of being written on the latter two categories: The sulfidal work involved odors (in descriptive terms) of rotton eggs, skunk, spoiled cabbage, etc., which are associated with simple mercaptons, sulfides and disulfides; the terpenoidal work involves odors (in descriptive terms) of earthy, woody, musty, floral, etc., and includes a variety of essential oils.

The earthy-smelling compounds isolated from blue-green algae and from various actinomycetes are not only the most widespread but also the most troublesome because extremely minute quantities render waters impotable. For this reason emphasis is being directed toward the resolution of the earthy-smelling compounds coupled with the determination of their metabolic production for control aspects.

In addition to developing biological growth units and sampling techniques, microanalytical techniques have been used and developed involving gas chromatography, infrared spectroscopy, mass spectrometry and PMR.

Cooperation with the local water purveyor has enabled an exchange of samples and information on actual reservoir waters.

2.0487, PROVISIONAL ALGAL ASSAY PROCEDURES
E.A. PEARSON, Univ. of California, School of Engineering, *Berkeley, California* 94720

Deterioration of surface water quality through eutrophication (increasing levels of nutrients resulting in increasing algal growth), has led to research to determine which factors are responsible for eutrophicatign or increased plant productivity. This project is concerned with the development of bioassay techniques for determining nutrient levels and for providing theoretical bases for relating bioassay results to the natural environment. The theory of algal growth is based on kinetic relationships between growth rate and concentration of the growth rate limiting nutrient. Such relationships should allow rational extrapolation of laboratory assay results to natural environments to permit estimation of the factor that limits growth and the concentration at which it becomes limiting. Two bioassay techniques, batch and continuous (chemostat) culture, are being compared and evaluated with respect to accuracy precision and convenience. The assays are performed under conditions of continuous light (400 f.c.), constant temperature (24 degrees C), and with unialgal test species. The results will be compared with results obtained by similar research studies at other laboratories, to permit selection of the most appropriate bioassay techniques for further evaluation under field conditions. This project commenced December 1, 1968 and will be terminated on January 31, 1971.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0488, THE SIGNIFICANCE AND CONTROL OF WASTEWATER FLOATABLES IN COASTAL WATERS
R.E. SELLECK, Univ. of California, School of Engineering, *Berkeley, California* 94720

The major objective of the study is to develop and evaluate quantitative methods for sampling and characterizing floatable materials of wastewater origin in the marine environment. These methods will be used to determine the pollutional significance of floatables and to suggest means of monitoring and control.

Floatables are described as either surface films or particulates. Surface films will be sampled quantitatively using screens of suitable materials and characterized by chemical, chromatographic and infrared techniques. Coliform concentrations will also be determined. Particulates will be collected by surface skimming, quantitated by weight and size distribution, and examined by microscopy. Floatables of natural origin will be distinguished from those of wastewater origin by comparing the characteristics of materials from a 'clean' control area with those of materials taken directly from wastewater and from the vicinities of marine outfalls. Mechanisms of sea slick formation and shoreward transport in coastal regions will be examined in situ to determine the flux of floatable materials between the sea and the shore, using tagged floatable materials.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.0489, ENVIRONMENTAL BIOLOGY OF TOMALES BAY
E.H. SMITH, Univ. of the Pacific, School of Arts, *Dillon Beach, California* 94929

The principal objective of the research is to learn how marine communities change in time under natural and artificial conditions. It must be stressed that the research now in progress has passed the faunal check list stage and moved into the investigation of individual organisms of groups or organisms and their relationship to the environment in which they are found. Such knowledge is required in order to evaluate and control the effect of man on the marine environment. Tomales Bay is one of the last unpolluted bays on the West Coast of the United States. The establishment of the Point Reyes National Seashore is expected to increase the artificial disturbance of the shallow water marine communities to an appreciable extent. It should be possible to observe the reciprocal effects between the increasing human population and the marine communities by maintaining a program monitoring the ecosystem. Data on physical and chemical parameters will be used to assess the relationship between the environment of individual organisms to the general environment of the region. This information can be used to reconstruct the pathways by which stress is applied to the community. Studies of functional morphology and environmental physiology will help to show how marine species react to changing conditions. The data acquired in these studies can be used to predict the impact of man on the marine environment elsewhere and to the ultimate feedback to human welfare.

2.0491, INSHORE FISHERIES HABITAT EVALUATION AND MONITORING
A.R. STRACHAN, State Dept. of Fish & Game, *Long Beach, California* 90802

This broad-based study will provide necessary guidelines for the protection and enhancement of nearshore areas with respect to the rapidly increasing activities of man, thereby aiding the Department in achieving its four stated objectives. Specifically, the major objectives of this Habitat Evaluation and Monitoring Program will be: (1) to document the present status of the nearshore marine animals and plants of California, their habitat, and needs in order to establish a basis for sound management policies relating to these living resources; and (2) to monitor, evaluate, and document changes to the biota, the environment, or both, as a direct or indirect result of man's activities, and to recommend action that will remedy situations that are found to be deleterious to the best interests of all concerned.

A general reconnaissance will be made of selected areas of the coast from the intertidal to 100-foot depths. The team of skilled biologists-divers will survey and map the geography of this subtidal zone. Notes, photographs, and reference bearings will be made. The small boats required in these operations will follow the divers as they survey the submarine topography, and will be used in taking bearings on terrestrial landmarks so the areas may be revisited.

These biologist-divers will also work on the backlog of contract surveys the Department has been requested to undertake, and conduct such immediate surveys (fire fighting surveys) that may be required of the Department during the fiscal year.

2.0492, HYBRID COMPUTER SIMULATION OF GROUND-WATER BASINS
W.J. KARPLUS, Univ. of California, School of Engineering, *Los Angeles, California* 90024

The purpose of the on-going research is three-fold: the primary objective is to establish the feasibility of employing a specialized hybrid (analog-digital) computing technique for the treatment of important mathematical and physical problems arising in ground-water pollution control. To this end a computational method developed at the University of California, Los Angeles has been implemented by constructing a special network specifically applicable to ground water problems. The resulting model is being applied to several ground-water problems existing in southern California. A second more general purpose of the research is to develop the technical skills required for a long-range attack on ground-water pollution problems. A subsidiary objective of the program is to provide a training ground for doctoral and master's engineering students so as to assure a supply of technical specialists adequately trained in the physics of ground-water control and in computer technology.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0493, ULTRAVIOLET ABSORPTION IN COASTAL WATERS
R.B. TIBBY, Univ. of Southern California, Allan Hancock Foundation, *Los Angeles, California* 90007

The proposed work revolves around the basic hypothesis that UV absorbance is a quantitative measure of the extent and dilution of a marine sewage field and that it is directly related to organic load and may be a better index to organic load than BOD.

Improved methods developed during the past year for determining dissolved, particulate and total carbon, and for separating the contributions of organic and inorganic constituents of the waste field and of the background waters, now will be applied in situ and in conjunction with the routine monitoring programs of

selected waste disposal agencies in Southern California whose discharge is subject to primary, secondary, or tertiary treatment.

The procedures also may provide information on the rates of biodegradation in the marine environment.

Present studies on the productivity of phytoplankton and benthic algae by oxygen evolution and isotopic carbon uptake will be continued, and will be correlated with the release of extracellular metabolites as determined by UV absorbance.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0494, INDUSTRIAL WATER POLLUTION CONTROL PROBLEMS

J.L. MACKIN, Stanford Research Institute, *Menlo Park, California* 94025

The general objectives of the current research are to identify and specify water pollution control problems in selected industries and to devise potential solutions to these problems. The longer term goal is to pool Institute resources and capabilities for assisting industrial and other clients in investigating the nature and control of water pollution problems arising from a wide spectrum of sources.

SUPPORTED BY Stanford Research Institute - Menlo Park

2.0495, AN ENVIRONMENTAL MONITORING PROGRAM FOR THE SACRAMENTO-SAN JOAQUIN DELTA AND SUISUN BAY

L.W. WEISBECKER, Stanford Research Institute, *Menlo Park, California* 94025

The monitoring program was developed as a comprehensive resource management information system, which would allow management policy for the resource to be based upon environmental consideratons.

Based on the present limited understanding of the resource, its uses, and their conditions and effects, the following minimum information needs were developed: 1. Continuous or weekly determination of 26 in-channel water quality and biological parameters for some 28 locations throughout the Delta, Suisum Bay, and San Pablo Bay. 2. Quarterly aerial surveillance photographic coverage of the Suisan Marsh be determine distribution and trends of marsh grasses as these affect suitability of the Marsh for waterfowl habitat. 3. Twice yearly aerial surveillance photographic coverage of the entire Delta to determine resource demand and use characteristics and to obtain an updated description of the Delta and an overall synoptic assessment of water quality conditions. 4. Continuous monitoring of all municipal, industrial, and agricultural waste water flow rates together with frequent sampling and determination of chemical, physical, and biological parameters that are related to receiving water quality. 5. Data related to resource demand and use from any available source on a continuing and current basis.

In addition an information handling system was specified that incorporates the functions of data processing, information storage and retrieval, modeling of the resorce, and a program that predicts the effects of resource use.

Recommendations were made for implementing and continually updating the program. Program costs were developed.

SUPPORTED BY California State Government - Sacramento

2.0496, ORGANIC SUBSTANCES IN WATER

D.F. GOERLITZ, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

Wide and complex varieties of organic substances are present in water and the number of the organic pollutants reaching water supplies is rapidly increasing. Knowledge of the extent, character, and composition of organic substances in water has lagged significantly behind that of the mineral components.

The work involves largely the development of methodology for the separation, identification, and measurement of organic substances in water. The initial work has been concerned with natural organic substances in water. The processes being developed basically involve extraction, vacuum evaporation, chromatography, and infrared spectroscopy.

The development of highly sensitive techniques for the separation, identification, and measurement of pesticides in water will be continued. Recovery studies will be continued and extended to cover additional pesticides to those already investigated. Efforts will also be directed toward the development of an electron capture gas chromatographic procedure for the analysis of chlorinated phenoxy acid herbicides and their derivatives in water.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0497, ARCTIC ENGINEERING GEOLOGY (NASA)

G.W. GREENE, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

States to which project pertains: Alaska.

Photographic and thermal infrared remote sensing surveys can provide valuable information concerning permafrost related engineering problems and can assist the engineering geologist in site selection and route planning in Arctic Alaska to demonstrate infrared techniques in the field, three test sites, each approximately 50 miles long and one mile wide, have been designated along the proposed oil pipeline route. These sites are typical of much of the terrain traversed by the pipeline.

During 1970 approximately 80% of the planned surveys were made. Adverse weather prevented completion of the field work. It is expected that the remaining field work will be done in 1971. One or more reports will be written also during 1971.

2.0498, SEISMOLOGICAL STUDIES - SANTA BARBARA

R.M. HAMILTON, U.S. Dept. of the Interior, Geological Survey, *Menlo Park, California* 94025

The present network should reveal which structures in the Santa Barbara area are seismically active at the present time. With the addition of critical channel-floor stations, it should provide sufficient precision in hypocenter determinations to reveal which, if any, of the faults through the channel oilspill area are moving. Such precision in hypocenter determination will be required if water flooding for increased oil recovery is to be carried out safely.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0499, DEVELOPMENT OF REMOTE-SENSING TECHNIQUES TO DETERMINE WATER QUALITY

G. GOODWIN, U.S. Natl. Aero. & Space Adm., Ames Research Center, *Moffett Field, California* 94035

The purpose is to develop remote sensing techniques which can be used to study the productivity, toxicity and turbidity of water bodies. The studies will provide a data base from which to evaluate local and global effects on marine ecology due to man-made and natural pollutants. Applications will include rapid determination of photosynthesis-induced productivity over large regions of the oceans, surveys of water quality following pollution abatement action, determination of presence and extent of a surface film as a toxic agent and barrier to oxygen transpiration, and delineation of tidal intrusions, currents, and water body boundaries. Airborne measurements will be performed to evaluate instrumentation such as a recently developed differential radiometer system (DRS) for operational use in determining chlorophyll, turbidity and surface films through unique reflectance or polarization characteristics. Laboratory studies will be conducted, for example, of thin films on the surface of water utilizing ellipsometry (polarization spectroscopy) techniques. Modification of these techniques to the remote identification of complex pollutant films on the surface of real bodies of water will be investigated. The investigator shown above is the Project Monitor whose telephone is 415-961-1111.

2.0500, ENVIRONMENTAL PROTECTION PROGRAM

R.N. STORER, U.S. Navy, Civil Engineering Lab., *Port Hueneme, California*

Technical Objective: To obtain, and organize pertinent information and data on current standards that apply to CONUS Naval facilities and to develop information on pollution control tests. Instrumentation and sensors for pollution ashore and in harbor and for non-ordnance deep water dumping. This will provide initial input to YF38.554.002. Data base for Navy pollution control to begin 1 July 1971.

SUPPORTED BY U.S. Dept. of Defense - Navy

2.0501, DEVELOPMENT OF NUCLEAR ANALYTICAL TECHNIQUES FOR OIL SLICK IDENTIFICATION

H.R. LUKENS, General Dynamics Corporation, *San Diego, California* 92112 (AT(04-3)-167)

The overall objective of the oil slick program is to develop nuclear and analytical techniques for oil slick identification. The first phase determined the feasibility of characterizing and identifying oil slicks by analysis of trace elements using Neutron Activation Analysis techniques.

The primary reason for this investigation is to provide the law enforcement agencies at various levels of Government the tools with which to enforce water pollution caused by releasing oil of any type from any source.

The work to be undertaken under Phase II is to characterize oils relevant to coastal waterways. The chief tasks are to obtain and analyze by Neutron Activation Analysis (NAA) a statistically satisfactory sampling of crude and residual oils that are as immediately related to the coastal-waterway pollution problem as possible, to subject the resulting data to statistical analysis, and to formulate probability statements that can be useful in coastal oil-slick identification work. The work will include an investigation of the suitability of samples from beached oil-slicks for identification purposes, and will include due consideration of the relative importance of oil seepages to the problem. Also, a practice test of a nuclear identification technique will be performed.

2.0502, GEOSECS - ACQUISITION AND CONSTRUCTION OF SHIPBOARD ANALYTICAL EQUIPMENT AND HYDROGRAPHIC AND SAMPLING SYSTEMS

A.E. BAINBRIDGE, Univ. of California, Graduate School, *San Diego, California* 92038

Considering the ocean as a source of food, a disposal area for nuclear and industrial waste products, and a controlling factor in the earth's climatic regime, our ultimate use of the sea is critically dependent on a detailed understanding of processes presently understood in only the vaguest and most qualitative way. These are the stirring and mixing processes in the deep sea, the interchange of material between deep and surface water, and the variation of organic productivity throughout the ocean, and the exchange of water and gases with the atmosphere. The GEOSECS program will measure in detail the oceanic constituents along Arctic to Antarctic sections at all depths, to provide, for the first time, a set of physical and chemical parameters measured on the same water samples. These data will provide the input for quantitative studies of oceanic mixing and organic productivity, and, at the same tme, serve as a baseline for the levels of pollutants and of fission and waste products being added to the sea. The Scripps Institution is responsible for supplying the shipboard computer, the salinity-depth temperature profiling system, hydrographic equipment, the shipboard gas chromatographic and titration systems, bottom water temperture and radon profiling system, Si32 collection equipment, rare gas and He3/He4 ratio equipment, and for the atmospheric, stable isotope, inorganic carbon, and dissolved gas analytical programs.

SUPPORTED BY U.S. National Science Foundation

2.0504, DISTRIBUTION OF RADIONUCLIDES IN THE OCEAN AND BEHAVIOR OF TRACE ELEMENTS IN THE OCEAN AND ORGANISMS (ABBREV)

T.R. FOLSOM, Univ. of California, Graduate School, *San Diego, California* 92038 (AT(04-3)34,Proj.)

Objectives: Following up our recent discovery of (127 year) Ag- 108m in certain 1964 marine biological samples toward better knowledge of albacore movements, turnover rates for metals, and stability of certain subsurface strata

Background: Recently Ag-108m was discovered in marine organisms we had analyzed in 1964 for Ag-110m. This dated a water mass used by the albacore and suggested the silver turnover rates for other organisms.

Procedures: Liver tissues analyzed with two-dimensional and summing spectrometers.

Continuation: Follow up by assaying for Ag-108m more old 1964 samples containing Ag-110m. Collect 1970 biological specimens, including albacore, for possible silver dating through recent Chinese tests. Continue procedure developments for Cs, Ag and Co using tissue samples.

Results: Exceptional concentrations of Cs in muscles of large fish has been demonstrated. Unexpected uniformity of natural cesium in the marine environment has been demonstrated. The usefulness of two silver nuclides for dating fallout movements has been discovered.

2.0506, THE DEGREE OF FECAL POLLUTION IN THE WATER OF REGIONS OF THE EASTERN DISTRICTS, BY A NEW COMBINED CHEMICAL-MICROBIOLOGICAL METHOD

L. TAN, Univ. De Sherbrooke, *Sherbrooke, Quebec, Canada*

Project (1) undertakes to develop combined methods, both practical and effective, for the detection of fecal pollution in water, using coprostanol and coprostanone as chemical tracers. Both of these are specific compounds in the intestinal system of

mammals. The chemical method is based on chromatographic analysis, both in thin layers and in the gaseous phase, while the microbiological analysis is based on the classical method of counting coliforms. Project (2) is a logical extension of (1). The three factories at Magog, East Windsor and East- Angue contribute visibly to pollution of the St. Francois and consequently of the St. Laurent. Nevertheless, the nature and extent of this industrial pollution are not well known. We propose to study this pollution, which risks injury to the health of the population. We wish to analyze by the methods of complexometry or atomic absorption all toxic elements, such as mercury and lead.

2.0508, OCEAN CIRCULATION
K. BRYAN, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302 (001146)

Technical Objective: To develop a comprehensive theory of the large-scale circulation of the ocean. The successful incorporation of the theory in the form of numerical models will be useful for pollution studies of large water bodies, long-range forecasting of sea-surface temperature, and joint air-sea model studies of the sensitivity of the earth's climate to large-scale atmospheric pollution.

Approach: Professional man years equal 5.0. The time-dependent models of the ocean will be studied in detail with a view of using them to pedict surface temperature. Tracer studies will be carried out to develop a tool for studying the uptake of excess CO2 by the ocean. Diagnostic studies with observed data will be carried out to determine more accurate formulas of turbulent mixing.

Progress: Hydrographic data has been assembled and interpolated on to a regular grid in preparation for diagnostic model studies of the Atlantic Ocean. Calculations have been extended, and a final write-up completed for a study of the Antarctic circumpolar current. Preliminary calculations have been made with a model of the World Ocean.

2.0509, STRUCTURE & MOTIONS - ATLANTIC
D.V. HANSON, U.S. Dept. of Commerce, Environ. Research Laboratories, *Boulder, Colorado* 80302 (011689)

To increase understanding of the physical, chemical and dynamical properties of coastal and ocean waters off the southeast coast of the U.S. to facilitate ESSA marine services in regard to tides and tidal currents, and transport of chemical constituents, heat, and pollutants by oceanic and coastal currents.

The principal study concerns the source of the Gulf Stream and the dynamics of circulation in the Gulf of Mexico. The major feature of this circulation will be studied by means of serial measurements of chemical and physical variables from the research vessels, Lagrangian current measurements using radar-transponder equipped drogue buoys, and surface temperatures sensed from earth satellites. Deep sea tide gauges and near bottom current meters will be used to test a theory of tides in the Gulf of Mexico proposed by Zetler and Hansen. Detailed attention will be directed to the influence of the Gulf Stream on the nearshore and estuarine environments.

Papers have been published on transport fluctuation and Lagrangian current observations in the Florida Current, and Gulf of Mexico tides. Studies of Lagrangian current measurements in the Gulf Stream south of Cape Hatteras, Gulf Stream meandering east of Cape Hatteras, evaluation of satellite data for observing varying positions of the Gulf Stream, coherence of large scale currents, and oceanographic conditions in the vicinity of Cay Sal Bank have been complete and submitted for publication. Data from two cruises in the Fall of 1969 await detailed analysis, but already provide information on the time scale of major circulation features in the Gulf of Mexico on which to base plans for future observations.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0510, WATER QUALITY ASSESSMENT AND POLLUTION CONTROL
S.S. SCHULTZ, U.S. Air Force, Frank J. Seiler Res. Lab., *Colorado Springs, Colorado* 80840

Technical Objective: AF function - environmental support of base operations (water quality/pollution control). Deficiency - USAF installations must implement a program of water quality monitoring to legally document their water pollution abatement programs in compliance with governmental water quality criteria as directed by AFR 161-22, Environmental Pollution Control. No model program exists to pattern such a comprehensive effort. Research - development of a water pollution abatement and monitoring program for the USAFA which will also be appropriate to USAF installations. How research contributes - a model water monitoring program will be developed which will include sampling networks, instrumentation, testing procedures and interpretation methods for determining the physical, chemical, and biological properties of water resources as part of the total environment pollution abatement and monitoring program. The objective of this research is to do the necessary research on methods and techniques and to develop a Water Quality Assessment and Pollution Control Program for the USAF Academy which will also be an appropriate model program for wide application in USAF pollution control programs. In addition, some specific problems in the USAF non-potable irrigation system will be investigated and their solution will have universal application of environmental pollution control such as: control of eutrophication in surface reservoirs, isolation and elimination of offensive odors in spray irrigation systems using treated sewage effluents, and ground water quality assessment and management. The model water quality monitoring program which should result from this research will provide a basis for legally documenting water pollution abatement programs as directed by AFR-161-22. It also will provide guidance on the manpower requirements and training essential for a continuing program for measuring, evaluating and controlling water pollutants of concern to the Air Force.

SUPPORTED BY U.S. Dept. of Defense - Air Force

2.0511, HYDRO- AND BIO-GEOCHEMISTRY OF HEAVY METALS
T.T. CHAO, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

States to which project pertains: Nationwide.

The principal objectives of this project are to elucidate the occurrence, distribution, and interactions of heavy metal elements in a water-sediment and soil plant system so that hydro- and bio-geochemical techniques may be developed for mineral exploration. The long-range work plans include the following: (1) Develop new methods for determining micro-quantities of certain heavy metal elements for exploration purposes; (2) establish the range of concentration and forms of occurrence of heavy metal elements in solution, in association with suspended materials, and in stream-bed sediments in a water system in mineralized and non-mineralized areas, (3) determine the response of these metals to environmental changes such as geological formation, ore deposits, water chemistry, chemical composition and mineralogy of stream-bed sediments, etc.; (4) study mechanisms of retention of a given metal element with different components of stream sediments; and (5) determine soil plant relationships in terms of heavy metal content in an area of known ore deposits.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0512, RIVER BASIN STUDY
D.A. HOFFMAN, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

Studies are needed to determine basinwide influences upon water quality. Data on selected water quality parameters from a series of reservoirs and streams within a given basin are needed to follow changes occurring in water quality. Specific programs will be developed to measure these parameters, evaluate new field instruments and techniques, devise better methods of analyzing the data, and determine the most effective ways for its use. Investigation of the basin-wide factors will be made on river basins selected for important features and functional characteristics.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0513, PREDICTING NITRATE CONTENT OF AGRICULTURAL DRAIN WATER
J.T. MALETIC, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

Conceptual model systems involving lysimeters and greenhouse work will be utilized to determine chemical reactions and movement of nitrogen from various sources. Soils of different origin and mineral composition will be used. Data from the model systems, plus data on nitrogen uptake of various irrigated crops secured from a search of the literature, will be used to develop a computer program for predicting the nitrogen transformations taking place in soil-water system under variations of time, moisture content of the soil, temperature, oxygen in soil air, source of nitrogen, or other factors. The computer program will be tested for reliability from data secured in a companion research contract at the University of California. The computer program will be applied in deriving estimates of the nitrogen content of drainage effluent from the San Luis Unit, Central Valley Project, California.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0514, ANALYTICAL METHODS - WATER CHEMISTRY
M.W. SKOUGSTAD, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

Analytical methods and techniques for many constituents that are found in water, such as aluminum, the halogenides, zinc, nitrate, nitrite, selenium, and detergents and other pollutants, frequently require modifications and refinements before they can be adopted specifically for water analysis. Improvements in all analytical procedures, including special instruments and techniques, are necessary to meet the requirements of expanding research efforts in the field of water chemistry.

The work consists of evaluating the potential of a technique and refining it to the minute concentrations significant in water chemistry. Fundamental chemical methods are studied as well as methods employing specialized equipment and instrumentation, such as X-ray and emission spectroscopy, electrometric, flame photometric and chromatographic instruments.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0515, PHYSICAL CHEMISTRY OF RADIOELEMENTS - RADIOMETRIC METHODS OF ANALYSIS
L.L. THATCHER, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

The objective of this project is to improve existing analytical methods and develop new analytical methods for the determination of trace concentrations of natural and synthetic radionuclides in water. Also, to make preliminary studies of determinations of trace concentrations of stable elements by activation analysis. Analytical techniques such as alpha and gamma spectrometry are used extensively. Frequently used chemical processes include ion exchange, solvent extraction, coprecipitation, and electrodeposition.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0516, TECHNIQUES AND INSTRUMENTATION - MONITORING LABORATORY
P.R. TRAMUTT, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

The principal purpose of this research is to develop and/or test new methods, techniques, and instrumentation that collect, analyze, and record water quality parameters for engineering and research needs.

The monitoring laboratory study will be directed toward developing a field laboratory kit that can be used by regional personnel for monitoring water quality data where only a limited number of parameters are to be measured. Also, part of this program will be the selection of analytical methods for use as acceptable standards for comparing our work with others.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0517, FIELD RESEARCH LABORATORY (MOBILE LABORATORY)
P.R. TRAMUTT, U.S. Dept. of the Interior, Bureau of Reclamation, *Denver, Colorado* 80225

This study will develop a mobile field laboratory that can be taken to the research site. The laboratory will be self-sufficient and capable of performing analyses for the usual chemical and biological parameters. Capability will also be provided for minor modification in order to handle analyses for unique and unusual parameters. The mobile laboratory is now being equipped with analytical instrumentation and equipment. The mobile laboratory will be put into full field operational use in water quality and ecology research studies after completion of shakedown trips. Provisions will be made to test the laboratory's usefulness for supporting other studies.

SUPPORTED BY U.S. Dept. of Interior - Bu. Reclamation

2.0518, RESEARCH TRACE METHODS
F.N. WARD, U.S. Dept. of the Interior, Geological Survey, *Denver, Colorado* 80225

Develop and study interferences in new methods of trace analysis that have potential use in applied mineral prospecting. Continuation of selective-ion electrode study to evaluate usefulness of such electrodes in following applications: 1. Iodide for iodine in igneous rocks to test feasibility of using iodine content as 'pathfinder' element. 2. Sulfide for indirect determination of mercury in water. 3. Fluoride for application of direct addition method for fluorine in soils, rocks, and water. 4. Copper for use of direct addition method for copper in water.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0519, DATA ACQUISITION SYSTEMS IN WATER QUALITY MANAGEMENT
L.R. FREEMAN, Colorado State University, School of Engineering, *Fort Collins, Colorado* 80521

This project will delineate the general objectives of a State Water Pollution Control Program and identify the types and quantity of information needed to accomplish these objectives. A survey of the state of the art of three water quality data gathering techniques (sampling/wet chemistry; electronic sensors; aerial surveillance) will be carried out to establish the capabilities, reliability and cost of each technique. A procedure will be developed for designing a state water quality monitoring program which is responsive to the state program objectives, and utilizes the best combination of the three data gathering techniques, subject to budget constraints. A water quality monitoring system will be designed for the State of Colorado to demonstrate the procedure.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0520, WATER QUALITY MANAGEMENT DECISIONS IN COLORADO
G.V. SKOGERBOE, Colorado State University, Environmental Resources Center, *Fort Collins, Colorado* 80521

The purpose of this work is to study the operation of the Colorado Water Quality program in order to develop a constructive critique which will assist in future program development. To accomplish this, the following objectives will be pursued: 1. Evaluate Colorado's present monitoring system for surveillance of stream standards with respect to both present and potential sources of pollution. 2. Evaluate the capability of present institutional programs to anticipate potential pollution problems and for

providing information necessary in decision- making regarding water quality management. 3. Evaluate present and projected institutional processes for pollution enforcement in Colorado, along with alternative methods for attaining conformance with stream standards.

Reliance will be placed upon case studies involving decisions by the Colorado Water Pollution Control Commission, together with policy statements and procedures established by that agency. Interviews will be conducted with parties involved in the selected cases to obtain attitudes with a variety of sources throughout the State, to assist in evaluating the present institutional processes for making adequate decisions, and to assist in evaluating the effectiveness of present enforcement techniques.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0521, A SYSTEM FOR GEOLOGIC EVALUATION OF POLLUTION POTENTIAL AT MOUNTAIN DWELLING SITES

J.P. WALTZ, Colorado State University, Environmental Resources Center, *Fort Collins, Colorado* 80521

The proposed research is to develop a hydrogeologic classification system for mountainous terrain. The classification system is to be designed for use in evaluating pollution potential at dwelling sites in the mountains.

Streams and wells in the mountains are susceptible to contamination because sewage disposal systems are usually privately owned and may be poorly situated or constructed. In addition, contaminated surface water can usually percolate directly into the ground via exposures of fractured or jointed rock. Also, direction and rate of ground water motion in a fractured medium are difficult to determine.

The procedure proposed for this research is to collect quantitative measures of topographic, geologic, and hydrologic variables. These data are to be used in a discriminant function analysis. The data will be in two groups: group I will contain information from sites where contamination has been documented and a source of pollution can be identified; group II will contain information from sites where no contamination can be detected, but where a pollution source is present.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0522, APPLIED ECOLOGICAL STUDY OF SPRING CREEK, FORT COLLINS, COLORADO

C.G. WILBER, Colorado State University, Agricultural Experiment Sta., *Fort Collins, Colorado* 80521 (COL00032)

OBJECTIVE: Study body of water adjacent to different types of land use areas. Information concerning the effect of different land use on natural water. Information for better advice on the application of ecological rules to land use planning.

APPROACH: Oxygen & temperature profile of stream recorded simultaneously from the source to the mouth at different times of the year. Study of pollution indicators such as tubificid worms will be made from some indication of the biological condition of the stream. The areas drained by the stream will be mapped and classified according to use. A study of the types and amount of invertebrates in different areas of the stream. Record the types and extent of solid waste dumped into the stream in different areas.

PROGRESS:

2.0523, AN ECOLOGICAL STUDY OF THE LOWER HOUSATONIC RIVER - PHASE I - SURVEY OF THE CHEMICAL ASPECTS OF THE RIVER

J.J. POLYHOWICH, Univ. of Bridgeport, Graduate School. *Bridgeport, Connecticut* 06602

The lower twelve miles of the Housatonic River will be sampled at six stations for both ecologically important and pollutant substances. Each week, a total of seventy two samples will be assayed for nitrates, nitrite, total phosphate, silica, oxygen, chloride, alkalinity, chromium, copper, iron, zinc, cyanide, detergents and hydrogen sulfide. In addition, turbidity, Seechi, BOC, and temperature measurements will be made at each station. The resultant data will be used to characterize this estuary with regard to its circulation patterns and the levels of the various polluting substances. This study is being conducted during the summer and early fall of 1970.

SUPPORTED BY Connecticut State Government

2.0524, SURFACE WATER TEMPERATURE OF THE CONNECTICUT RIVER

R.A. JONES, State Board of Fish. & Game, *Hartford, Connecticut* 06115

Objectives: 1. To profile on a seasonal basis the surface temperature of the Connecticut River from Wilder, Vermont to its mouth at Saybrook, Connecticut. 2. To detail surface water temperatures of certain areas of the Connecticut River which may influence the restoration of anadromous fish. Surface temerature isotherms will be plotted in areas of heated effluents, other heat sources and temperature depressing tributaries.

Procedures: Temperature determinations will be obtained with a Barnes Model PRT-5 infrared radiation thermometer and recording equipment mounted on S-46 helicopter owned and operated by the State of Connecticut, Department of Aeronautics.

Over-flights will be made at altitudes of 100 feet or less on a monthly basis from April through November. One day each month up-river flights will be made from Saybrook, Connecticut to the vicinity of Wilder, Vermont. During these flights, the river to Hartford will be crisscrossed using marine navigation aids and man-made structures as reference points. Above Hartford the flight will be essential mid-river using man-made objects and topographic features as reference points.

After a review of the average temperature profile at the completion of the up-river flight, a detailed survey will be made at points of temperature rise and depression; such as heat effluents, impoundments and tributaries during the return flight. Certain major tributaries will be surveyed to provide data to correlate with main stem temperature patterns.

Data will be plotted as an average temperature profile along the length of the study area against river miles and man-made features. Detail survey data will be plotted as isotherms in the areas of interest. Completed temperature information will be utilized as base data for future analysis as regards recommendations to regulatory agencies on location and allowances for heat producing industries. Data will also be used to provide information on the cause and magnitude of thermal loading from various sources such as steam electric plants, manufacturing operations and solar energy in areas of impoundments and shallows related to hydroelectric operations.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0525, DEVELOPMENT OF INSTRUMENTAL TECHNIQUES FOR THE ANALYSIS OF TRACE ORGANIC CONSTITUENTS IN WATER

R.P. COLLINS, Univ. of Connecticut, Graduate School, *Storrs, Connecticut* 06268

The proposed research plan involves the development of more effective methods for isolating, concentrating, identifying and measuring trace organic constituents in public water supplies. Improved and highly refined instrumentation is needed for this purpose because of the ever increasing amounts of highly complex organic constituents which are being introduced into water supplies and for which, at the present time, no techniques exist for their detection or measurement.

Laboratory investigations would test the usefulness of the following analytical procedures: a. Coupled gas-chromatography and mass spectroscopy. b. On-column trapping procedures. c. Coupled gas chromatography and rapid scan infrared spectroscopy. d. Thin-layer chromatography. e. DEAE column chromatography for isolating and concentrating high molecular weight organic constituents.

Upon completion of the laboratory phase the analytical procedures developed would be used in sampling Connecticut rivers and reservoirs in which difficulties from industrial effluents and/or objectionable tastes and odors had been experienced.

2.0528, ANALYTIC AND PROCESS CLASSIFICATION OF EFFLUENTS (ORGANIC NITROGEN IN ACTIVATED CARBON EFFLUENTS)
T. HELFGOTT, Univ. of Connecticut, School of Engineering, *Storrs, Connecticut* 06268

This research involves testing of effluents to classify the residual organics in terms of chemical analyses and process behavior. The residual organics, as measured by total organic carbon content, in the effluents of activated carbon treatment have been found to contain cationic organics. This implies the presence of nitrogen in an amino acid or quaternary form. These residual organics maintain cationic characteristics even at high pH above the isoelectric point of most amino acids except for a few basic amino acids. This information has been found by use of a modified electrodialysis/electrophoresis technique. Tests in this research are to confirm directly that the residual organics in activated carbon effluents contain organic nitrogen. Plans involve collection of sewage effluent, treatment with activated carbon, concentration and fractionation of the residual organics by gravitational electrodialysis and the analysis of the nitrogen of the concentrated fractions.

Part of this research activity involves the use of a total nitrogen analyser and the development of this instrument to distinguish organic and inorganic nitrogen.

The significance of this information is that only after the refractory components of waters are detailed can the most effective and efficient treatments be practiced and the ecological and public health considerations be known.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0529, BEHAVIOR OF STREAM INSECTS
S.W. HITCHCOCK, Univ. of Connecticut, Agricultural Experiment Sta., *Storrs, Connecticut* 06268 (CONH00308)

OBJECTIVE: Gain knowledge of the behavior of representative species of stream insects, especially as related to changing conditions in the stream. Study migration and dispersal of immature stream insects. This has particular importance in gaining information on repopulation of streams denuded by drought or pollution.

APPROACH: Methods of measuring movement upstream will be developed and comparisons made between a permanent stream and an intermittent stream. An attempt made to correlate with laboratory studies of upstream movement.

PROGRESS: Routine sampling continued to measure recovery in the streams following drought. This work is completed and awaits tabulation, summary, and preparation for publication. Because of three years of drought, the original plan as outlined could not be followed, but information was gained on survival in these streams. In the stream dry to its source, apart from those insects normal to an intermittent stream, recovery in numbers and genera proceeded upstream. In the stream that was dry for only part of its length, recovery moved downstream. Those insects with short life cycles and able to survive in intermittent streams suffered less predation than those in permanent streams. This is due to the drought-induced destruction of insect predators which require a year or more of larval life.

SUPPORTED BY U.S. Dept. of Agriculture

2.0530, VARIABILITY IN DIATOM MORPHOLOGY AND WATER POLLUTION
F.R. TRAINOR, Univ. of Connecticut, School of Liberal Arts, *Storrs, Connecticut* 06268

The purpose of the present investigation is twofold: (1) to study the morphological and growth responses of freshwater diatoms to changes in the physical and chemical environment using the culture technique, and (2) to study morphological variability in laboratory cultures of diatoms incubated in natural waters. If we can demonstrate in controlled laboratory experiments as well as in cultures incubated under 'natural' conditions morphological responses of an organism to changes in environment, we would expect certain morphological types to be indicators of the chemistry of the water. Among the environmental components which will be investigated are: levels of inorganic nutrients, levels of available CO2, presence of certain organic substances, pH, temperature, and light.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0531, A MULTI-PHASIC COMPONENT STUDY TO PREDICT STORM WATER POLLUTION FROM URBAN AREAS
P.R. WALTERS, Avco Economic Systems Corp., *Washington, District of Columbia* 20006 (C-1743)

Storm water surface runoff not only may cause local damage by flooding, but also by polluting the receiving streams. Improved techniques are needed to predict the quality as well as quantity of storm water runoff in an urban area for application to planning and better control of pollution, evaluation of requirements for hydromechanical structures as well as the design of treatment systems.

The proposed research will develop methodology for predicting urban area water pollution. Parametric models will determine pollution levels from land activity and environmental factors. This will afford an area- wide spectra analysis of pollution.

The model system will enable analysis and assessment of pollution conditions, benefits, and cost of alternative remedial measures to include conveyance and treatment as well as management practices to control pollution. Also included is a demonstration of the methodology in selected metropolitan areas to validate its feasibility and practicability as a tool for planning, management and control of urban area storm water pollution. It is anticipated that the project will be started in September 1969 and will be completed in September 1970.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0532, VIBRIO PARAHAEMOLYTICUS IN CHESAPEAKE BAY - ISOLATION, INCIDENCE AND PATHOGENICITY
R.R. COLWELL, Georgetown University, School of Arts, *Washington, District of Columbia* 20007

This project will continue an investigation of the incidence and pathogenicity of the bacterial pathogen 'Vibrio parahaemolyticus' in marine and estuarine animals, with particular emphasis on the Chesapeake Bay blue crab, 'Callinectes

sapidus'. The animals, sediment and water will be sampled periodically and any resulting bacteria will be identified. Information on the natural flora of estuarine and marine invertebrate animals will be collected in a format suitable for computer analysis so as to provide a basis for understanding the interaction amongst the micro-organisms constituting the commensal flora. The pathogenicity of any 'Vibrio parahaemolyticus' isolates for crabs, shrimp and mice will be determined.

SUPPORTED BY U.S. National Science Foundation

2.0533, POLLUTION CONTROL IN THE MARITIME ENVIRONMENT

G.C. NICHOLS, U.S. Dept. of Commerce, Natl. Bureau of Standards, *Washington, District of Columbia* 20234

To identify the magnitude and other characteristics of marine- related water pollution, such as sources and causes of pollution, types of pollutants, quantities and locations of spills, in the New York harbor area. To determine additional data which should be incorporated in future incident reports. To develop correlations between significant components of the water pollution problem and determine probabilities of occurrence of potential spills. If time and data permit, to develop methodology for estimating potential risk (or expected loss) resulting from accidental spills of one or more pollutants deemed to be of major significance. To examine the type of data available in pollution incident reports filed with the Coast Guard, the Corps of Engineers, the FWQA, the Port of New York Authority, the American Petroleum Institute, and other sources for the period January 1967-June 1969. To establish a format for coding the data contained in these reports. To collate the data gathered from the various sources to eliminate double-counting and identify the dimensions of the water pollution problem in the area. To analyze the data obtained according to source and causes of pollution, types and quantities of pollutants, geographical location of spills, and other important factors, and develop a few significant cross- tabulations. To evaluate the quality of the data currently available and indicate deficiencies in these data. If time and money permit, to explore the feasibility of forecasting future accidental spills.

SUPPORTED BY U.S. Dept. of Commerce - N.B.S.

2.0534, GEOCHRONOLOGY, C-14 METHOD

M. RUBIN, U.S. Dept. of the Interior, Geological Survey, *Washington, District of Columbia* 20242

States to which project pertains: all.

The dating by C-14 of samples pertaining to changing climates will continue, pursuant to the primary objectives of the project. Emphasis will be made on dating tectonic movements, to determine rate of movements on global plates. Construction of sea level curves from all over the world will be continued. Some dating of ground water for general problems in movement is contemplated. Magnetic dipole oscillations during the Wisconsinan glaciation will be measured from any rapid-deposited sediment unit. Pollution studies on rivers and oceans will be undertaken to determine contribution of 'dead' and 'modern' carbon to the total carbon carried in solution and in particulate form.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0535, ULTRAVIOLET STUDIES (SOLAR-STIMULATED FLUORESCENCE)

G.E. STOERTZ, U.S. Dept. of the Interior, Geological Survey, *Washington, District of Columbia* 20242

States to which project pertains: Not applicable for areal data; testing was over California and Arizona.

Instruments and techniques are sought for remotely detecting substances that fluoresce when irradiated by sunlight. A prototype Fraunhofer line discriminator (FLD) operating at the amber sodium-D2 line (5890 angstroms) has been converted to operate at the blue hydrogen-F line (4861 A). Conversion to the deep red hydrogen-C line (6563 A) is commencing.

The sodium-D2 FLD proved useful as an airborne or shipboard fluorometer over water, measuring substances that fluoresce amber, such as rhodamine dyes. Rhodamine WT was monitored in concentrations below 5 ppb in clear river water, moderately turbid marine coastal water, and highly turbid estuaries.

Airborne tests over water were conducted over San Francisco Bay, San Pablo Bay, the Bonita Channel west of Golden Gate, and the Colorado River near Needles, California. Airborne tests over land were conducted over southeastern California and west-central Arizona.

Ultimate objectives are to develop capability to monitor pulp- and papermill effluents by the fluorescence of lignin sulfonates, the distribution of phytoplankton by chlorophyll fluorescence, and to monitor other pollutants such as oil spills, detergents, or chemical wastes.

Objectives include development and testing of airborne instruments and survey techniques, of accessory laboratory apparatus and techniques, and of data-compilation procedures to permit either qualitative or quantitative applications of remote fluorescence analysis.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0536, STANDARD MONITORING SECTIONS A-6 AND A-7 CRUISE AND AIGIST 1970 NERVE GAS DUMP SITE SURVEY

W.T. ADAMS, U.S. Dept. of Transportation, Coast Guard, *Washington, District of Columbia* 20591

On 12 November 1970 the USCGC ROCKAWAY (WAGO 377), CDR William T. ADAMS, Commanding, will depart Governors Island, New York to occupy Coast Guard Monitoring Sections A-6 and A-7 and to survey the August 1970 Army nerve gas dump site. A concurrent monitoring of Section A-5 will be conducted by the USCGC (WHEC 39) upon returning from Ocean Station ECHO.

Standard Monitoring Sections A-5, A-6 and A-7 cross the Gulf Stream and are occupied several times each year by the Coast Guard in an attempt to define the seasonal variations of this current system. The Salinity-Temperature-Depth (STD) sensor will be used to gather oceanographic data along the sections. STD casts by the CGC ROCKAWAY will be supplemented with Nansen casts to near bottom periodically.

The nerve gas dump site survey will be made about 20 - 21 November 1970. The data gathered during this cruise, coupled with the deep water data gathered during the actual dump period by the USCGC MENDOTA (WHEC 69), should provide insight into the possible distribution of the selected parameters related to nerve gas, its degradation products and its effect on the marine environment in the area of the dump site. During both the occupation of stations on the Sections A-6 and A-7 and the dump site, data will be gathered to show the vertical distribution of temperature, salinity, oxygen, fluoride, nitrates, phosphates, silicates and ammonia.

SUPPORTED BY U.S. Dept. of Transportation - Coast Guard

2.0537, WESTERN BEAUFORT SEA ECOLOGICAL CRUISE (WEBSEC 9-70)

T.L. ROBERGE, U.S. Dept. of Transportation, Oceanographic Unit, *Washington, District of Columbia*

On 23 September 1970, the USCGC GLACIER (WAGB 4), Capt T. L. Roberge commanding, will depart Point Barrow, Alaska, to conduct a cooperative baseline assessment of the biological, chemical, geological and physical variables of the marine ecosystem in the coastal waters of the Western Beaufort Sea (Cape Halkett to Barter Island). Particular emphasis will be placed on the area near Prudhoe Bay. The duration of the survey will be approximately one month.

The Western Beaufort Sea, adjacent to the North Slope oil field, is an area in which the likelihood of future pollution is great. All too frequently, investigations of the impact of pollution on the marine ecosystems are conducted without any quantitative knowledge of the ecosystems in their unpolluted state. The lack of such knowledge seriously limits the analysis and interpretation of data taken after pollution has begun. It is imperative that a quantitative assessment of the variables of the ecosystem be undertaken as soon as possible.

At least two cruises must be conducted to obtain an estimate of normal seasonal variation in the ecosystem. One cruise will be conducted this autumn at the end of the open water season and another at the beginning of the open water season (mid-July 1971).

SUPPORTED BY U.S. Dept. of Transportation - Coast Guard

2.0538, COMPLETION OF AN ECOLOGICAL SURVEY CRUISE IN THE SOUTHEASTERN CHUKCHI SEA

T.L. ROBERGE, U.S. Dept. of Transportation, Coast Guard, *Washington, District of Columbia* 20591

From 23 September to 18 October 1970, the USCGC GLACIER (WAGB 4), Capt. R. T. Roberge Commanding, conducted a cooperative ecological cruise in the Southeastern Chukchi Sea. The objective of this cruise was to conduct an assessment od chemical, physical, biological, and geological conditions in the marine environment as baselines for comparison with future conditions in the event of pollution. Because of the relatively advanced state of development of the North Slope oil field, the principal area of interest was the western Beaufort Sea. The eastern Chukchi Sea, not yet the site of development, was an alternative area. The presence of extensive pack ice in the vicinity of Point Barrow precluded sampling operations in the Beaufort Sea: accordingly the cruise was conducted in the Cape Lisburne-Icy Cape area of the southeastern Chukchi Sea.

The following scientific organizations participated in the cruise: U. S. Coast Guard Oceanographic Unit, Washington, D.C; U. S. Geological Survey, Menlo Park, California; U. S. National Marine Fisheries Service (formerly BCF) Laboratory, Auke Bay, Alaska; U. S. Bureau of Sports Fisheries and Wildlife, Anchorage, Alaska; Smithsonian Institution, Washington, D. C. and the Institute of Marine Science, University of Alaska, College, Alaska.

Ninety-two stations were occupied during the cruise yielding the following data or samples: 47 Nansen bottle casts for temperature, salinity, and nutrients; 136 NBT Drops; 14 Niskin bottle casts for geochemical water samples and nutrients; 28 Current meter lowings for 130 hours; Surface meteorological observations on station; 60 Vertical zooplankton tows; 81 Mid-water trawls; 33 Box cores; 12 Metal-free gravity cores; 71 Grab samples of bottom sediments; 4 Piston cores; 3 Isotopic oxygen water samples; 4 Microplankton tows; 14 Beach profiles; 2 Airborne particulate samples; 68 Transmissometer lowerings; 42 Bottom camera lowerings; 100 Hours of bird and mammal survey; 66 Birds collected; 7 Mammal species identified.

All data will be published, with a description of sampling methods and a preliminary interpretation, in the USCG Oceanographic Report Series (CG-373).

2.0539, HYDROLOGY, USDI

M. DEUTSCH, U.S. Natl. Aero. & Space Adm., *Washington, District of Columbia*

The hydrologic problems have been divided into 4 study classes: (1) inland hydrologic features, (2) quantities and physical properties of snow and ice (3) estuarine and coastal hydrologic features and (4) water quality parameters. The purpose of the hydrology program is to develop an automated data collection, processing, analysis and distribution network utilizing both remote sensor (air and space) and ground control data. A real-time network of ground monitor stations will be selected from about 50,000 data collection stations presently maintained by the USGS water resources division in cooperation with all 50 states, and numerous federal, interstate and local agencies. The investigator shown above is the Project Monitor whose telephone is 202-382-4423.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

2.0540, NATURAL AND CULTURAL RESOURCE MANAGEMENT

A.B. PARK, U.S. Natl. Aero. & Space Adm., *Washington, District of Columbia*

Department of Interior Bureaus are progressing on feasibility studies of the application of earth resources satellite data and associated space technology to operational functions of the department. These studies are in eight broad task areas each consisting of several discrete projects: 1. Land classification for reclamation planning and management, including water logged irrigation land, tropical land irrigation classification, arid land weather modification, water and land resources for classification of arid irrigation lands, weed control for irrigation management, water quality flow for irrigation, intense rainstorms and water management development of system for utilizing ERTS data for reclamation, soil engineering, and improved snow survey. 2. Land use classifications and resource inventories for multi-bureau requirements including application of space systems to public land inventories, public timber and spruce beetle control, resource inventory of Papago Indian Reservation, use of ERTS data by computer for Indian affairs, and cadastral surveys of public lands. 3. Oil leaks and slicks, including applications of NASA's fraunhofer line discriminator to oil and water pollution problems. 4. Ecology of Wetlands and Uplands Wildlife Habitat Areas, including use of ERTS data for wildlife refugee management, and the use of space imagery and technology for game areas and coastal zone fish and crustacean breeding areas ecology studies. 5. Inventory, preservation, management of national parks using space technology, and including archaeological site development. The investigator shown above is the Project Monitor whose telephone is 202-133-6523.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

2.0541, SPACECRAFT OCEANOGRAPHY PROJECT

A.B. PARK, U.S. Natl. Aero. & Space Adm., *Washington, District of Columbia*

Since 1965, the Naval Oceanographic Office and the National Aeronautics and Space Administration have been conducting, through a formal working agreement, a research program to define feasible ocean measurements from space platforms. Broad consideration of applicable remote sensors to measure ocean features has resulted in a concentrated effort to define the oceanographic goals for the next several years with regard to space systems. Basically, this project has narrowed funding requirements for research to define sensor, observational and data requirements for a satellite bearing the following systems: (A) MOCS- Multichannel ocean color system, (B) Time-thermal infrared mapping system, (C) AWODs-all weather ocean dynamics system. These sensor systems will obtain data on all ocean features evaluated to date the remote sensing from space. This project also recognizes the value of the data collection system (DCS) which has been successfully used for interrogating surface platforms, as a complimentary system to remote sensing. Research for justifying and specifying the sensor systems, observational requirements and data handling techniques for the above systems is divided into five categories: (1) Ocean color via visible region sensors. (2) Sea temperature or thermal charting via infrared (and microwave) sensors. (3) Ocean dynamics-primarily with microwave sensors with secondary visible and infrared vision sensors. (4) Specific ocean applications such as sea ice, shoals, food-from-the-sea, pollution and coastal (processes) ecosystems. and (5) Management. A coherent program for developing requirements in all these areas has been presented to the National Aeronautics and Space Administration (NASA). This is the only national effort of its kind in oceanography as not similar programs exists in the Department of Defense, the National Aeronautics and Space Administration or elsewhere. The investigator shown above is the Project Monitor whose telephone is 202-963-6523.

2.0542, TAXONOMY AND ECOLOGY OF INSHORE MARINE MICROBIOTA

J.B. LACKEY, Unknown Inst. Or Indiv. Grant, *Florida*

This envisages publication of an illustrated account, with keys, of inshore marine and brackish water protozoa and microscopic algae, both planktonic and benthic. Their commonness or rareness, cosmopolitan or restrictive distribution will be covered by ecology, especially with reference to pollution, nutrient richness and water poor in nutrients. Regions covered to date are

the Atlantic Coast, Florida to Woods Hole, Massachusetts; the Florida Gulf Coast, the California Coast, the Island of Oahu and Guanabara Bay, Brazil.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0543, ST. JOHNS RIVER FISHERY PROJECT

H.L. MOODY, State Div. of Game & Fish, *Eustis, Florida* 32726

The purpose of this study is to monitor fish populations of the entire St. Johns River for fishery conservation purposes.

The rapid rate of human population growth in this section of Florida has produced and is continuing to cause limological and terrestrial changes, through public works and other activities, which has adverse effects on the fishery of the river. The aim of this study is to define these changes more precisely in order that deteriorations of the fishery may be arrested or prevented.

Fish population samples are taken with various standard fishing gear and by different methods, including chemicals, to determine successive changes in the populations and their species composition which may be related to natural environmental factors, water pollution, or to artificial changes in the habitat. Studies of sportfisherman success, harvest rates and fishing pressure are also made.

SUPPORTED BY Florida State Government - Tallahassee

2.0544, MEASUREMENT OF ELEMENTS DEPOSITED FROM ATMOSPHERE

C.L. DANTZMAN, Univ. of Florida, Agricultural Experiment Sta., *Gainesville, Florida* 32601 (FLA-RC-01382)

OBJECTIVE: Determine the amount of chlorine, fluorine, iodine, and sulfur brought down from the atmosphere in rainfall.

APPROACH: Rainfall will be caught in stainless steel rain gauges and collected in acid-leached jugs. The jugs will be changed monthly and analyzed for the elements in question.

PROGRESS: Water sampling of nine streams and six bodies of water within a radius of 50 miles of the Range Cattle Station began in January 1969 and continued at one-month intervals. Rainwater collecting from five sampling stations continued. All water samples were analyzed for Al, Ca, Cl, Cu, F, Fe, I, K, Mg, Mn, P, Na, Zn, and soluble salts. Quantities of the elements were found to vary during the year for all sampling stations including streams, lakes, and rainwater.

SUPPORTED BY Florida State Government - Tallahassee

2.0545, STUDIES ON THE METHANOGENIC BACTERIA IN SLUDGE

P.H. SMITH, Univ. of Florida, School of Agriculture, *Gainesville, Florida* 32601

Experiments are being conducted to describe the methanogenic microflora in sludge. A large number of pure cultures of methanogenic bacteria have been isolated and their characteristics determined.

Experiments are being conducted to determine quantitatively the roles of fatty acids in the digestion process.

A culture collection of methanogenic bacteria has been established containing all extant cultures of methanogenic bacteria. The cultures are available to interested investigators through the American Type Culture Collection.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0546, ENZYME SYSTEMS OF ESTUARINE ORGANISMS

D.L. COPPAGE, U.S. Environ. Protection Agcy., Office of Res. & Monitoring, *Gulf Breeze, Florida* 32561

Two of the major classes of pesticides - the organic phosphates and the carbamates - are toxic to animals because they inhibit the enzyme acetylcholinesterase (AChE), which is essential to normal nerve impulse transmission. By assaying the AChE activity in nerve tissue of aquatic animals, pollution of the estuarine environment by these chemicals can be detected before deaths occur and at levels far below those which can be detected by present analytical techniques.

We will establish normal enzyme levels for selected vertebrate and invertebrate species, and conduct periodic sampling and assay. Lowered enzyme activity in one or more species will be indicative of pollution. We will also expose various fishes and invertebrates to commonly used pesticides to study degree of AChE inhibition and time necessary for recovery. An investigation of the effects of lowered enzyme levels on estuarine fauna will be conducted.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0547, WATER QUALITY AND FUNGI-NEMATODE-SEAGRASS-RELATIONSHIPS

J.W. FELL, Univ. of Miami, School of Marine Science, *Miami, Florida* 33149

Environmental conditions in Biscayne Bay are being altered rapidly through continued urbanization and industrialization. However, studies on the existing food web and sources of productivity, adequate to provide a baseline for planned development and use of this natural resource, have not been made. Initial observations suggest that the mangroves lining the shores and the macro-algae and sea grasses of the shallow bay bottom produce such large quantities of detritus that they constitute the major source of productivity. It also appears likely that this material is made available in a form utilizable by the invertebrates and fishes principally through fungal degradation. The fungi in turn may be grazed by nematodes and other small invertebrates co-habiting the detrital sediments. The specific roles of fungi and nematodes however, are not known and it is important to examine these organisms in the natural environment and to determine the effects of environmental variables on this food chain sequence. Anticipated environmental changes are likely to include large quantities of heated water, industrial and human wastes and the destruction of fringing mangroves by bulkheading.

The following aspects will be studied: 1) distribution of human pathogenic yeasts and their potential use as pollution indicators; 2) effects of thermal effluents on fungal and nematode populations; 3) role of fungi and nematodes in estuarine productivity, specifically in the mangrove system.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0548, GEOSECS RADIOCARBON AND TRITIUM MEASUREMENTS

H.G. OSTLUND, Univ. of Miami, School of Marine Science, *Miami, Florida* 33149

Considering the ocean as a source of food, a disposal area for nuclear and industrial waste products, and a controlling factor in the earth's climatic regime, our ultimate use of the sea is critically dependent on a detailed understanding of processes presently understood in only the vaguest and most qualitative way. These are the stirring and mixing processes in the deep sea, the interchange of material between deep and surface water, the variation of organic productivity throughout the ocean, and the exchange of water and gases with the atmosphere. The GEOSECS program will measure in detail the oceanic constituents along Arctic to Antarctic sections at all depths, to provide, for the first time, a set of physical and chemical parameters measured on the same water samples. These data will provide the input for quantitative studies of oceanic mixing and organic productivity, and, at the same time, serve as a base-line for the levels of pollutants and of fission and waste products being added to the sea. Ostlund will concentrate on C14. If measurements are made with higher precision than currently available, C14 holds the greatest wealth of information as the most important oceanic radio tracer, because it is involved in both the inorganic-organic carbon cycle and the general circulation problem. Ostlund requires considerable support to environmentally condition facilities to assure highly precise (plus or minus 4 per mil) and reliable results.

2.0549, UPPER ST. JOHNS WATER QUALITY, FLORIDA

D.A. GOOLSBY, U.S. Dept. of the Interior, Geological Survey, *Tallahassee, Florida* 32304

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with State and local agencies in Florida and the Corps of Engineers.

Purpose: To determine the types and sources of contaminants in waters of the upper St. Johns River basin as an aid in evaluation of water management proposals.

Methods: Seasonal sampling, with concurrent measurement of discharge, is proposed for about 20 sites in the basin and specific conductivity profiles along main stream and tributaries run to determine sources of contamination. Field and laboratory determinations will be made and besides the customary determinations of common minerals will include dissolved oxygen, pH, nutrients, pesticides and trace elements.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0550, REMOTE SENSING, EVERGLADES AREA, FLORIDA
M.C. KOLIPINSKI, U.S. Dept. of the Interior, Geological Survey, *Tallahassee, Florida* 32304

Purpose: To determine the relations between water conditions and biological populations in the Everglades by interpretation of airborne data and to develop new applications in natural resources research for data from remote sensors.

Methods: Spectral reflectance measurements of floral communities and water will be obtained using an airborne 18-channel optical- mechanical scanner. The data will be accumulated in a form that will allow use of a computer to identify and map the distribution and amount of selected communities. Remote sensing data will be examined for potential in: detecting plankton blooms, locating alligator holes, and estimating populations of large animals.

2.0551, PRODUCTIVITY AND MINERAL CYCLING ON NATURAL AND MANIPULATED ECOSYSTEMS
D.A. CROSSLEY, Univ. of Georgia, School of Agriculture, *Athens, Georgia* 30601

Major objective of this research involves an intensive study of water quality, productivity and nutrient cycling on natural and manipulated ecosystems at U. S. Forest Service Coweeta Hydrologic Laboratory. Initial research will concern annual and seasonal input- output of water and nutrients of four watersheds. Dissolved and particulate materials reaching the weir ponds will be sampled regularly. Feasibility of several sample alternatives will be examined for measuring particulate losses. Emphases will be placed on the successional weed stand, 6 year coppice stand and 13 year pine catchment areas.

SUPPORTED BY U.S. National Science Foundation

2.0552, ENTERIC BACTERIAL DEGRADATION OF STREAM DETRITUS
C.W. HENDRICKS, Univ. of Georgia, Graduate School, *Athens, Georgia* 30601

At the present time many of our clean fresh water lakes and streams are receiving pollutant materials from various agricultural, industrial and municipal sources. It is currently believed that if the dilution rate is sufficiently small, little permanent damage results to the body of water in question. However, many of these materials can serve as substrate for the growth and multiplication of organisms which are presently indicators of fecal pollution and can cause disease. The major objective of this proposal is to conduct basic research on mechanisms by which enteric bacteria, including pathogens, can survive in the aquatic environment. Particular attention is now being given to the understanding of the growth - promoting activity of various substrates which are either indigenous to the aquatic environment or are artifically introduced and to describe the conditions which will influence the rate of turnover of both bacterial populations and substrates. Techniques which allow for the direct measurement of oxygen uptake of metabolizing bacteria are now being employed to yield data concerning those natural substrates which can support the growth of enteric bacteria. Our preliminary results appear to be sufficient to being the continuous culture experiments which should give us infc mation about growth yields on these substrates. Once specific information has been obtained concerning the utilization of this material, we would be in a better position to understand the roles of both the aquatic environment and the bacteria in a polluted stream. Such data could also aid in the classification of rivers and streams and form a foundation for the construction of model systems which might be able to predict the theoretical pollution limits of a given body of water. It is conceivable that this type of knowledge could yield useful data on how presently contaminated bodies of water can be reclaimed.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.0553, FLUORESCENT PROBES IN THE DEVELOPMENT OF NEW ANALYTICAL METHODS FOR WATER POLLUTION
C.M. HIMEL, Univ. of Georgia, School of Arts, *Athens, Georgia* 30332

The major objective of this research is the study of the application of designed fluorescent probe molecules with cholinesterase enzymes in the detection of insecticides at low levels in water.

Fluorescent probe molecules which are equilibrium inhibitors of the anionic site of Ch.E. have been synthesized. 1-(5-Dimethylaminoaphthalene-1-sulfonamide) 3-N, N dimethylaminopropane and its aliphatic quaternary derivative act as active-site-directed, equilibrium fluorescent probes at the anionic site of Ch.E. The presence of the probe molecule at the active site interferes with the binding of certain phosphate type and chlorinated hydrocarbon type insecticides. The degree of interference is reflected in the fluorescence spectral response of the probe-enzyme complex.

Sensitivity of the analytical method is determined by the relative concentrations of the enzyme and the fluorescent probe. It is also related to the equilibrium constants for the dissociation of the probe- enzyme complex and the insecticide-enzyme complex. Indicated sensitivity is in the range of 10 to minus the 8th power or less at present.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0554, TRACE ELEMENT ANALYSIS BY DIRECT DETERMINATION ON ION EXCHANGE RESINS
D.E. LEYDEN, Univ. of Georgia, School of Arts, *Athens, Georgia* 30332

The objective of this research will be to develop sensitive and accurate procedures for the analysis of akaline earth, transition metal and heavy metal ions in aqueous solutions. This method of analysis involves the use of selective ion exchange resins and subsequent determinaton of the retained ions by direct analysis of the resins by X- ray spectrography. Application of the method will be made to many diverse subject areas including analytical chemistry, water pollution, oceanography, trace element geochemistry and geochemical prospecting. The method has been successfully applied to the analysis of barium in water and in aqueous NaCl solutions containing from 10 to minus super 4 to 10 minus super 8 moles. Preliminary studies have shown the feasibility of applying this method to other alkaline earth elements and to the transition metals copper and zinc. Research will be concentrated on the development of procedures for further applications of commercial resins and to test and to develop other specific ion exchange resins to meet particular analytical problems. Methods for analyzing solids will be developed as well as for solutions.

SUPPORTED BY U.S. National Science Foundation

2.0555, DETERMINATION OF DEGRADED DYES AND AUXILIARY CHEMICALS IN EFFLUENTS FROM TEXTILE DYEING PROCESSES
R.K. FLEGE, Georgia Inst. of Technology, Water Resources Center, *Atlanta, Georgia* 30332

Work will be directed toward the development of methods for identification and quantitative measurement of dyes and chemical auxiliaries, in raw and treated textile mill effluents.

Chromatographic and indirect spectrophotometric methods of analysis will be investigated. Methods developed will be extended to cover residues, from those dyes and chemicals, originating from reactions in the dyebaths or waste treatment processes.

Dyeing formulae will be made up from widely used dyes and auxiliary chemicals. Analytical methods will be developed for identification of those known dyes and chemicals.

Effluents from commercial dyeing processes, that make use of chemicals in the model formula, both before and after conventional waste treatment, will then be analyzed in an attempt to determine the degradation product of those dyes and chemicals resulting from waste treatment processes.

Processing formulae using known dyes and auxiliary chemicals will be subjected to laboratory waste treatment techniques, simulating those used for treatment of domestic waste in conventional treatment plants and lagoons. Effluents from these experiments will be analyzed for presence of original dyes and auxiliaries and their forecasted degradation products.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0556, PREDICTION MODELS FOR WATER QUALITY PARAMETERS

W.W. HINES, Georgia Inst. of Technology, Water Resources Center, *Atlanta, Georgia* 30332

This proposal is the second phase of a project entitled 'Prediction Models for Water Quality Parameters.' Phase II will build on the results of Phase I work. Phase II objectives are, first, to quantify the feedback and control mechanisms that exist in the total water quality system of a basin or region (the qualitative feedback network is developed as a part of Phase I); and, second, combining the quality parameter interaction (between dissolved oxygen and temperature) model from Phase I, which describes stream quality resulting from various uses and waste discharges, with the feedback control system mentioned above, general system behavior under different policies will be studied.

The need for Phase II has become clearer as Phase I has progressed. Considerable work has been done and is now in progress on various components of the total water quality system; e.g., the research being performed in Phase I on the prediction of the stream quality component. It is known that social, economic, and political conditions and attitudes influence the amount of waste discharge to streams, and the water quality standards result from needs and desires of the various public and private sectors, etc. Therefore, in order to put water quality planning and management on a more rational and more socially equitable basis, the various water quality system components must be embedded in a comprehensive system which is capable of relating the actions and decision of each segment to those of the others. This approach will be of assistance in setting water quality standards that can be reasonably attained, since the total system response can be studied and changes made in the proposed standards prior to putting them into effect.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0557, APPLICATION OF MODERN ELECTROANALYTICAL TECHNIQUES TO THE ANALYSIS OF HEAVY METALS IN WATER

P.E. STURROCK, Georgia Inst. of Technology, Water Resources Center, *Atlanta, Georgia* 30332

The proposed research plan involves laboratory and field investigations directed at determining the suitability of modern electroanalytical techniques for the analysis of water for trace contaminations by heavy metals. The approach will be to determine the sensitivity limits, accuracy and interferences for a number of metal ions using solutions of known concentrations prepared in the laboratory. Then the procedures and techniques developed will be tested on samples obtained from various points along the Chattahoochee River to see if point to point and day to day fluctuations of heavy metal concentrations can be observed.

Laboratory investigations will employ the following methods: 1. Square-wave polarography. 2. Phase-selective A.C. polarography. 3. Derivative chronopotentiometry.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0558, HYDROLOGY OF COASTAL AREA IN THE VICINITY OF RICEBORO, GEORGIA

J.R. GEORGE, U.S. Dept. of the Interior, Geological Survey, *Atlanta, Georgia* 30309

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of Georgia.

Purpose: To determine the hydraulic and chemical characteristics of surface waters in the North Newport River Drainage Basin and the piezometric surface and quality of water in the principal artesian aquifer in the vicinity of Riceboro prior to the beginning of operations of a large industry as well as after the plant is in operation.

Methods: The tidal behavior of the Newport River estuary will be studied and the amount of interchange between salt and fresh water, the time of travel through the estuary, and the dispersion patterns will be determined. Discharge measurements will be made. Chemical analyses will be made on water samples collected periodically and water quality monitors will be installed. Wind direction and velocity component data will be recorded at one station. Continuous water level recorders will be installed on four wells. Electric and gamma-radiation logs will be made of selected wells within 30 miles of Riceboro to determine the amount of casing and depth of the well and aid in interpretation of the geology and identification of the aquifer. Aquifer tests will be made at the plant site after completion of the plant wells.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0559, DISSOLVED OXYGEN AND OXYGEN DEMAND IN A SALT MARSH BORDERED ESTUARY

D. FRANKENBERG, Univ. of Georgia, Marine Institute, *Sapelo Island, Georgia* 31327

The project supported with this grant describes and analyzes dissolved oxygen an oxygen demand distributions, with respect to time and space, in a small unpolluted, estuary bordered by a salt marsh, the Duplin River of Sapelo Island, Georgia. The relationships between the distributions of dissolved oxygen and oxygen demand and the distributions of physical, chemical and biological parameters in the estuary are tested statistically through multivariate analysis in order to generate mathematical and computer simulation models of dissolved oxygen and oxygen demand phenomena. The predictive value of these models is tested by their application to the Dulpin River and to larger, more complex estuarine systems nearby. In addition, the results of this research will provide important base lines from which the effects of stresses imposed on a salt-marsh estuary by unusual processes (those which alter oxygen concentrations) can be measured.

SUPPORTED BY U.S. National Science Foundation

2.0560, A STUDY PROGRAM TO IDENTIFY PROBLEMS RELATED TO OCEANIC ENVIRONMENTAL QUALITY - NORTH ATLANTIC

D.W. MENZEL, Skidaway Inst. of Oceanograph., *Savannah, Georgia* 31406

This project to identify the major problems of man's contamination of the oceans will be carried out in two parts: (1) Samples of the ocean environment including zooplankton, fishes (migratory and non-migratory), benthic organisms sediments, sea water, surface slicks, and airborne material will be analyzed for pollutants (heavy metals, transition metals, pesticides, and petroleum derived hydrocarbons). (2) Following completion of the above program, a study group will be convened in Woods Hole to discuss the results and to interpret them. The final product will be the planning document for a full-scale research program in the Environmental Quality of the North Atlantic Ocean. Skidaway Institute of Oceanography will have primary responsibility for analysis of benthic organisms, zooplankton and sediments for heavy metal concentration. The Institute will play a leading role in the Part II Study. Dr. Menzel will be responsible for the overall management of the program.

SUPPORTED BY U.S. National Science Foundation

2.0561, COMMERCIAL OYSTER FISHERY DEVELOPMENT INVESTIGATION
H.M. SAKUDA, State Div. of Fish & Game, *Honolulu, Hawaii* 96813

The objectives of this phase are to: 1) Continue experimental commercial oyster growing operations and assist private growers in improving production; 2) Determine the effects of adding chemical fertilizers to the growing waters in respect to oyster production; 3) Continue monitoring of the oyster growing waters to establish the sanitary quality of various potential cultural sites; 4) Conduct marketing studies to determine consumer demand; 5) Conduct relaying and short-term depuration studies in commerical quantity and determine durations required to cleanse oysters so that a standard relaying and depuration period can be established for Hawaiian waters.

The work will be conducted mainly in West Loch, Pearl Harbor and at the Molii Fishpond under a cooperative agreement with the pond operator.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.0562, EVAPOTRANSPIRATION BY SUGAR CANE
P.C. EKERN, Univ. of Hawaii, Water Resources Research Ctr., *Honolulu, Hawaii* 96822

Field data from the installation of a large semi-contained hydraulic lysimeter within a major irrigated sugar cane region at the Kunia substation of the Hawaiian Sugar Planters' Association will be given laboratory analysis for correlation of the measured rate of consumptive use with pan evaporation and other soil and meteorological parameters suitable for prediction of irrigation interval scheduling.

Other activities: Calibration of this instrument as a primary standard for the measurement of evaporation from water, Latosol, and successive growth stages of sprinkler irrigated sugar cane; assessment of the patterns of moisture movement within the lysimeter and measurement of the heat budget within the soil; calibration of the neutron probe for tropical soils; and collection of seepage waters for detection of the rate of movement of nitrates and other constituents through the profile into the ground water.

Methods used: A 6 m square, 2 m deep container with walls of fiber glass reinforced resin, supported on an hydraulic scale of nylon reinforced irrigation hose will comprise the lysimeter. Batteries of resistance blocks, tensiometers, and access tubes for neutron probe will be arrayed for in situ record of soil moisture status. A similar array of thermistor units will record temperature gradients within the lysimeter soil. Porous ceramic tubes will be used to maintain soil water suction equivalent to 100 cm of water at the bottom of the soil column. Percolate waters withdrawn through this system will be preserved for qualitative analysis. Correlative studies will be made of the long period (24 hour) water use rates with pan evaporation and other predictive parameters. Short period (hourly rates) will be assessed as reflected in cane growth, particularly in the presence of temporary mid- day wilt.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0563, BACTERIOLOGICAL STUDY OF THE POLLUTION OF KANEOHE BAY, OAHU
K.R. GUNDERSEN, Univ. of Hawaii, Water Resources Research Ctr., *Honolulu, Hawaii* 96822

A comprehensive study of coliform distribution and other indicator bacteria of sewage origin will be made of the water in Kaneohe Bay, Oahu, Hawaii including hydrological and meteorological observations.

Six sites near sewage outfalls and in the Bay will be sampled at two water depths and of the bottom deposit. Sewage just prior to disposal will also be sampled. All liquid samples will be collected at least weekly and with aseptic technique. Liquid bottom samples will be analyzed for coliforms 35 degrees C, thermostable 45 degrees C, enterococci 35 degrees C and total count 25 degrees C. Prior to sampling, air and water temperatures, wind direction and speed, cloudiness, rainfall, water turbidity will be measured.

This study is expected to provide the much needed data for determining the degree of sewage treatment required and for a planned study of the bacterial involvement in the transformations of inorganic nitrogen and sulfur compounds in the Bay.

SUPPORTED BY University of Hawaii

2.0564, GEOSECS - ISOTOPIC MEASUREMENTS (C13/C12O18/O16DH) IN DISSOLVED INORGANIC CARBON, ATMOSPHERIC CO2 & H2O VAPOR & DISSOLVED O2 (ABBREV)
P.M. KROOPNICK, Univ. of Hawaii, School of Arts, *Honolulu, Hawaii* 96822

Considering the ocean as a source of food, a disposal area for nuclear and industrial waste products, and a controlling factor in the earth's climatic regime, our ultimate use of the sea is critically dependent on a detailed understanding of processes presently understood in only the vaguest and most qualitative way. These are the stirring and mixing processes in the deep sea, the interchange of material between deep and surface water, the variation of organic productivity throughout the ocean and the exchange of water and gases with the atmosphere. The GEOSECS program will measure in detail the oceanic constituents along Arctic to Antarctic sections at all depths, to provide, for the first time, a set of physical and chemical parameters measured on the same water samples. These data will provide the input for quantitative studies of oceanic mixing and organic productivity, and, at the same time, serve as a base-line for the levels of pollutants and of fission and waste products being added to the sea. This proposal covers the construction of (1) sea-going systems for extraction of dissolved O2 and CO2 from sea water for isotopic analysis, (2) shipboard systems for collection of atmospheric CO2, N2O, and water vapor, and (3) laboratory system for conversion of dissolved O2 stripped from sea water to CO2 for mass spectrometric analysis. Isotopic analyses and N2O measurements will be done in collaboration with the Isotope Laboratory at Scripps Institution of Oceanography.

SUPPORTED BY U.S. National Science Foundation

2.0565, POLLUTION OF COASTAL WATERS
L.S. LAU, Univ. of Hawaii, School of Engineering, *Honolulu, Hawaii* 96822

Coastal waters undoubtedly constitute one of the most important natural resources in Hawaii. In spite of the importance of existing and potential pollution of the coastal waters, knowledge of the extent of such pollution and its effects in these waters in Hawaii is extremely meager. The objective of the proposed investigation is to plan an overall program of research on the pollution of Hawaiian coastal waters, intended to provide a satisfactory knowledge base for a sound water quality control program. The provision of knowledge might be approached by a combination of several possible routes: pollution survey, ecological surveys, waste discharge case studies, and single pollutant studies. The pollution effects would be subjected to economic analyses and appraisal of esthetic effects, and implications in controls and institutional management. The general procedure would be organization of an interdisciplinary steering committee of university faculty, a renowned water pollution expert as executive secretary and additional out-of-state specialists as short-term consultants. Through continuing studies and/or workshops, review will be made of pollution patterns, parameters, pollution effects, waste discharges, transport mechanisms, fates, and the adequacy of present water quality standards. Liaison will be maintained with other state programs and other Sea Grant programs especially coastal zone management.

2.0566, IDENTIFICATION OF IRRIGATION RETURN WATER IN THE SUBSURFACE
R.H. YOUNG, Univ. of Hawaii, Water Resources Research Ctr., *Honolulu, Hawaii* 96822

The proposed project will summarize in a comprehensive report the physical and chemical characteristics of return irrigation

water derived from areas of tropical agriculture. Sampling will be continued from the Kalauao and Kahuku areas of Oahu and from the isthmus and West Maui ground water areas. Both composites and profile samples will be obtained from complete analyses including determinations of pH, chloride, sulfate, nitrate, phosphate, silica, hardness, bromide, iodide, fluoride, and boron. Basic data collection will necessitate sampling of rainwater, surface run-off, bulk-fallout and spring water. Some tritium studies for flow-tracing and age-dating will be utilized. The total water quality information will be correlated with fertilization and irrigation practices and land use patterns to ascertain man's contribution to the basal water, to identify patterns of ground water flow, rock weathering, chemical erosion, and for formulation of water quality standards and/or water management practices.

2.0567, INVESTIGATION OF MICROLAYER COLLECTION FOR POLLUTION MEASUREMENT

G.W. HARVEY, Oceanic Institute, *Waimanalo, Hawaii* 96795

Objective: To determine the effectiveness of the microlayer collector with its associated analytical methods for sampling, detecting and tracing pollutants at the air-water interface in Hawaiian waters.

Large (18-liter) samples will be collected simultaneously from the 60-micron and the 10-centimeter levels along suspected gradients of pollution in Kaneohe Bay, Oahu, with controls from the very clean oceanic water outside the Bay. Samples will be held for not more than one hour so that degradation will be minimized.

The high concentrations of organic material in the surface microlayer have suggested it as a site for detecting and monitoring pollutants. Our past work has shown unexpectedly large quantities of bacteria, algae, protozoa and other organic and inorganic particles in this region, with possible and specific relationships to marine pollution. At least five possible indicator organisms have been found in the 60-micron layer.

Fluorometry, atomic absorption and conventional spectrophotometry will be employed for chemical analyses, supplemented by some standard methods for oil residues. High resolution and interference contrast microscopy with special chambers, will be used for most of the particle analysis.

2.0569, DETERMINATION OF THE DISTRIBUTION OF RADIONUCLIDES DISCHARGED TO THE GROUND AT THE NRTS, IDAHO

J.T. BARRACLOUGH, U.S. Dept. of the Interior, Geological Survey, *Idaho Falls, Idaho*

Program is a continuation of that conducted in previous years. The observation of migration of the radioactive isotopes contained in the aqueous wastes has been a primary part of the program. Underground movement has not yet reached a steady state and observations will continue until steady state is reached. The program consists of observation of radionuclide migration and is determined from empirical analysis of data on aquifer discharge effects observed as water level fluctuations in wells to tracer studies using both natural and introduced elements to determine both vertical and horizontal movement, determination of head differentials between aquifers and single wells and between wells and bore hole geophysical logging.

2.0570, EFFECTS OF URBANIZATION ON GROUND-WATER SUPPLIES, BOISE AREA, IDAHO

N.P. DION, U.S. Dept. of the Interior, Geological Survey, *Idaho Falls, Idaho*

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of Idaho.

Purpose: To provide a detailed description of the ground water resources of the Boise-Nampa area in southwestern Idaho and to assess the effect of urbanization on this source of water supply.

Methods: The hydrology of the shallow aquifers extending to depths of about 200 feet will be evaluated on the basis of their occurrence and the availability, source, movement, and quality of the water they contain. This will be accomplished by (1) collecting construction, water-level and chemical quality data and driller's logs for selected wells, (2) constructing geohydrologic diagrams showing the lateral and vertical extent and lithology of hydrologic units, (3) using hydrographs and piezometric maps to show short-term water level fluctuations, long term trends, areas of recharge and discharge, and the elevation and configuration of the water table, (4) collecting water samples for chemical analyses to show the distribution of various chemical types of water.

The effects of urbanization will be assessed by seeking to establish the nature and location of changes, if any, in groundwater recharge, movement, discharge, and quality using current and historical data. Extensive use will be made of aerial photos taken in 1953 and in 1969 to determine changes in land-use and water-use patterns.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0571, ECOLOGICAL FACTORS INFLUENCING FREE-LIVING NITROGEN-FIXING ORGANISMS IN CERTAIN NORTHERN SOILS

G.R. ANDERSON, Univ. of Idaho, Agricultural Experiment Sta., *Moscow, Idaho* 83843 (IDA00214)

OBJECTIVE: Determine whether or how Azotobacter propagate in the main streams and irrigation systems of southern Idaho. Identification and classification of Azotobacter from plot and soil studies. Determine if Azotobacter can serve as an indicator of the toxicity of fluorine effluents.

APPROACH: The ecology of these organisms in Portneuf soils and related irrigation waters will be studied. The effect of nutrients and climatological factors on Azotobacter in native waters will be followed through population changes. Unusual Azotobacter in native waters will be followed through population changes. Unusual Azotobacter isolates from natural and artificially induced populations will be identified. The particular effect of fluorides on Azotobacter strains will be measured in soil, water, and laboratory cultures, using a fumigation chamber.

PROGRESS: Field soils of Palouse and Moscow silt loam were thoroughly mixed with Beijerinkia, moistened and reburied in plastic bags in the field. A population increase of three log values was noted in all glucose (.5%) amended soils. These populations figures were obtainable only as a result of dilution plating on acid nitrogen free, acid nitrogen free with 50 ppm Fungizone and Martin's alkaline nitrogen free media. Inhibited growth on soil plates at low dilution was routine. Studies of old field plots in Moscow silt loam revealed the absence of Beijerinkia regardless of soil preparation. Azotobacter populations increases of 10 were noted without inoculum and with a minimal natural population. Plot counts of Beijerinckia from distilled water dilution bottles revealed the apparent increase in Beijerinckia in distilled H(2)O over a period of three months or more. Air inoculation of Southern Idaho soils by Nitrogen fixers was measured. Nitrogen-fixers. Pseudomonas, Cladosporium and other unidentified organisms, were recovered from the impinger. No Azotobacter were found indicating that Azotobacter are not usually transported from soil to soil through the air.

SUPPORTED BY U.S. Dept. of Agriculture

2.0572, AN INVESTIGATION OF FACTORS RELATIVE TO GROUND-WATER RECHARGE IN IDAHO

R.E. WILLIAMS, Univ. of Idaho, Graduate School, *Moscow, Idaho* 83843

Location of those communities in Idaho producing appreciable volumes of wastewater has been determined in an earlier investigation by these researchers. The objective of the immediate

study is the examination of several hydrogeologic environments which in the future may be affected by wastewater disposal and recharge. Information on soils, groundwater, natural recharge, and geology will be obtained for several localities. Analysis of these data will facilitate recommendations concerning recharge and irrigation and the effect of these two processes on surface and ground-water environments.

At least one waste disposal operation will be examined in detail. The role played by the soil and rock as a renovating agent for wastewater will be examined at the locality of the disposal project.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0573, AN INVESTIGATION OF FACTORS INFLUENCING WATER QUALITY IN SOUTH FORK, COEUR D'ALENE RIVER

R.E. WILLIAMS, Univ. of Idaho, State Bureau of Mines & Geol., *Moscow, Idaho* 83843

The quality of the South Fork of the Coeur d'Alene River, Idaho, reportedly has been degraded by various users. However, little study of the river, its quality or the sources of its pollution has been undertaken. This study is designed to define the pollutants, determine their concentrations, their sources, and to recommend corrective measures.

SUPPORTED BY Idaho State Government

2.0574, CONTAMINATION OF DRINKING WATER AS A POSSIBLE FACTOR IN RETARDATION OF GROWTH OF SUCKLING CF1/AN1 MICE

M.P. FINKEL, Argonne National Laboratory, *Argonne, Illinois* 60439 (W-31-109-38)

A test is being run to determine whether drinking water was responsible for a disease that appeared suddenly in the CF1/An1 breeding colony 7-8 years ago. The colony had been in excellent condition before several lactating mice died, and soon after that many suckling mice were undersize, apparently because they were not getting enough milk. Mice that survived to weaning age often were able to grow subsequently to normal size, and when they were bred, their reproductive performance was not different from that of mice not so severly retarded early in life. Infection seemed not to be the cause, and change of diet and bedding material had no effect. After several years autoclaved demineralized drinking water was substituted for autoclaved tap water, and growth of suckling mice has almost returned to normal. To test the hypothesis that a pollutant in the laboratory tap water becomes toxic to lactating mice upon autoclaving, breeding pairs of mice are being maintained on autoclaved demineralized water, autoclaved tap water, or fresh tap water. The experiment will be carried for 3-4 generations. Reproductive performance is being measured by number of litters and number of offspring produced, number weaned, and weight at weaning.

Results: Most of the original breeding pairs have produced one or two litters, and several second generation mice have reached reproductive age. There are not enough data at this time, however, to indicate whether drinking water was responsible for the disease manifested by failure of suckling mice to grow normally.

SUPPORTED BY U.S. Atomic Energy Commission

2.0575, ELECTROCHEMICAL METHODS FOR THE DETERMINATION OF TRACE AMOUNTS OF PHOSPHATE IN NATURAL WATER

J.A. COX, Southern Illinois University, School of Technology, *Carbondale, Illinois* 62901

The electrochemical techniques of stationary electrode polargraphy and cathodic stripping voltammetry are being investigated as possible means of trace analysis of phosphate.

The former method requires the formation of an electrochemically reducible phosphate complex; initial work will involve phosphomolybdic acid. The latter technique requires reversible deposition of phosphate as an insoluble salt on an electrode. Copper will be initially employed since a film is known to be formed on this metal in phosphate solution.

2.0576, BIOLOGICAL SURVEY OF STREAMS OF COLES COUNTY, ILLINOIS

L. DURHAM, Eastern Illinois University, Graduate School, *Charleston, Illinois* 61920

This study is designed as a systematic survey of the fish, macroinvertebrate and plankton populations of the streams in Coles County in east-central Illinois. It is intended to provide a basis for comparison studies of the future, in particular, following the construction of a flood-control reservoir which is in the land acquisition stages. The stations sampled have been carefully designated and mapped to allow exact duplication of areas sampled in the future. Thus the effects of such reservoir construction and function on stream populations may be observed. Data being collected include certain aspects of water quality including standard tests for D.O., temperature, pH, hardness, alkalinity, NO3, NO2, SO4 and PO4. BOD's and coliforms are being determined periodically. Examination of these data should also provide information concerning possible sources of pollution to the reservoir. Discovery and identification of such sources may allow remedial measures to be carried out before the reservoir reaches the filling stages. This project was initiated in June, 1967 and will be terminated in June, 1970.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0577, DETECTION OF OIL CONTAMINATION IN SEA WATER

G.L. JOHNSON, I I T Research Institute, *Chicago, Illinois* 60616

An instrument is being constructed and tested for continuously monitoring the concentration of suspended persistent oil and oily residues in fresh or salt water in the range 100 to 1000 plus or minus 10 ppm. Infrared absorption spectrometry is employed. The third harmonic of the methylene group at 1.21 Mu is employed because the small hydrocarbon absorption coefficient here makes optical density independent of particle size, and because the small water absorption coefficient here permits a water thickness sufficient for a flowing sheath of clean water. The sheath prevents contact between oil and optical windows. A lead sulfide sensor observes alternately at the absorbing wavelength and the mean of a pair of low absorption flanking wavelengths, to discriminate against non-spectrally selective or broadly selective interference, i.e. displacement of absorbing water by transparent solutes or particulates, scattering losses, and variation in source color temperature. A second sensor observing an out-of-phase signal provides common-mode rejection of noise due to non-oily (transparent) particulates, and cross-talk from a duplexed I sub o signal.

SUPPORTED BY U.S. Dept. of Commerce - Maritime Admin.

2.0578, A PRELIMINARY INVESTIGATION OF THE ROLE OF SEDIMENTS IN EUTROPHICATION

M.L. SILVER, Univ. of Illinois, School of Engineering, *Chicago, Illinois* 60680

The objective of this research is to perform a feasibility study that will aid in determining the amount and type of association between sediments and the phosphate nutrients responsible for the acceleration of eutrophication in rivers and lakes. Aquatic sediments may act as stable phosphate reservoirs under certain conditions; however, natural or man made disturbance that destroys this equilibrium may release unacceptably large quantities of nutrients back into the water.

The first phase of the investigation will determine, from the literature, the present state of knowledge concerning where phosphates occur in sediments, what are the quantities held, how the phosphates are held, and what mechanisms exist for dislodging phosphates from sediments. A second phase of the research will perform laboratory tests to define the manner in which phosphates are retained in sediments under conditions encountered in aquatic environments. In addition, the feasibility of using techniques such as X-ray diffraction and P sub 32 tracer techniques to measure various interaction mechanisms will be determined. The development of techniques for determining

where and why this nutrient is held or released should provide techniques for the future study of the fates of similar pollutants.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0579, SAND AND GRAVEL AQUIFERS OF NORTHEASTERN ILLINOIS

J.E. HACKETT, State Geol. Survey, *Urbana, Illinois* 61801

The region under investigation consists of Lake, McHenry, Cook, DuPage, Kane, and Will counties, and makes up the greater Chicago metropolitan area. Subsurface data and surficial mapping have been the basis for identifying and mapping surficial, interbedded and basal sand and gravel aquifers. The mapped aquifers are at least 15 feet thick. Surficial aquifers are overlain by 10 feet or less of fine grained sediments. Interbedded aquifers are overlain by more than 10 feet of fine grained sediments and are underlain by 10 feet or more of fine grained sediments above the top of the bedrock. Basal aquifers are underlain by less than 10 feet of fine grained sediments above the top of the bedrock. The mapping criteria lead to a delineation of the more favorable areas for large ground-water developments from sand and gravel. Mapping of the position of the aquifers relative to land surface facilitates understanding of hydrologic conditions and consideration of possibilities for artificial recharge and ground-water pollution.

SUPPORTED BY Illinois State Government - Springfield

2.0580, METHODS IN SPECTROGRAPHIC ANALYSIS OF SOILS & PLANTS FOR MINOR ELEMENTS

S.W. MELSTED, Univ. of Illinois, Agricultural Experiment Sta., *Urbana, Illinois* 61801 (ILLU-15-0361)

OBJECTIVE: Improve and adapt methods of spectrographic analyses to polluted drainage waters, study methods of soil and plant samples preparation to permit use of emission spectrograph, x-ray fluorescence and atomic absorption techniques and continue cooperative evaluations of spectrographic methods, prepare large standard plant material samples for cooperative analysis and referee work.

APPROACH: Methods of chelation and chemical separation to remove interferring contaminants will be studied. Possibility of pelletizing soil and plant borate and metaborate fusions for x-ray fluorescence and subsequent dissolving for spectrographic and atomic absorption will be investigated. Large ten-pound samples will be dried, ground and thoroughly mixed for cooperative analysis and selection for future use in calibrating methods and referee work.

PROGRESS: The spectrographic analyses of soils fused with sodium metaborate and then dissolved in nitric acid shows considerable promise for combining x-ray fluorescence and emission spectrographic analyses with a single sample preparation technique. The use of nitric acid, rather than hydrochloric acid, to acidify polluted water samples while being concentrated for spectrographic analysis improved the accuracy of such analyses. Present procedures are not entirely satisfactory for waters high in lead and chromium. The method for spectrographically determining Ca, Mg, K and Al in ammonium fluoride (P-1) soil extracts is reasonably satisfactory. A method for the analyses of horseradish was also worked out.

SUPPORTED BY U.S. Dept. of Agriculture

2.0581, THE SEPARATION AND IDENTIFICATION OF TRACE ORGANICS OF INDUSTRIAL ORIGIN IN NATURAL WATERS

V.L. SNOEYINK, Univ. of Illinois, School of Engineering, *Urbana, Illinois* 61801

The proposed research involves the use of concentration techniques followed by gas chromatographic separation and spectrometric characterization and analysis of certain organic pollutants of industrial origin. The pollutants to be examined are these aromatic polycyclic and heterocyclic compounds not naturally found in the environment.

Various concentration techniques such as freeze concentration, solvent extraction, and adsorption will be used to obtain a sample suitable for separation by gas chromatography or other chromatographic techniques. The separated fractions will then be identified by mass spectrometry, infrared spectrophotometry, or other applicable spectrometric methods.

These laboratory techniques will be developed using a synthetic water containing concentrations of selected compounds typical of those found in industrial effluents and waste streams. The most successful techniques will then be used to detect and trace pollutants in a natural water system.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0582, HYDROLOGY AND WATER QUALITY OF SURFACE MINING FOR COAL IN PIKE COUNTY, INDIANA

D.G. FREY, Indiana University, Water Resources Research Ctr., *Bloomington, Indiana* 47401

The project area is in southwestern Indiana, in the area where Coals No. 4 and 5 have been strip-mined for many years.

Two automatic recording steam gaging stations have been established, and partial flow measurements will be taken at 6-8 sites; water quality samples will be taken at these and perhaps 50 other locations, particularly in the South Fork Patoka River.

The project was begun in September 1964, and a report (Indiana University Water Resources Research Center Report of Investigations No. 1, 1965) was published; the project was expanded to include a detailed study of quantity and quality of water in the Busseron Creek Watershed of Sullivan County (Report of Investigations No. 2 is due in September, 1968), and to include reconnaissance investigations in fringe areas. The current project will continue the reconnaissance in a few of the fringe areas.

SUPPORTED BY Indiana University - Bloomington

2.0583, WATER POLLUTION STUDY OF THE WABASH RIVER

J.M. BELL, Purdue University, School of Engineering, *Lafayette, Indiana* 47907

Studies were initiated to develop a comprehensive surveillance program on the quality of the Wabash River between Lafayette and Covington, Indiana. Data is collected at a critical time of the day throughout the summer months of low flow.

An attempt is being made to obtain a mathematical model(s) which may be used to predict the response of the dissolved oxygen concentration in the river to the waste discharges resulting from municipalities, industries, and agriculture sources in the Greater Lafayette Area.

SUPPORTED BY Purdue University - Lafayette, Ind.

2.0584, ECOLOGIC IMPACT OF HUMAN ACTIVITIES ON WATER RESOURCE ENVIRONMENTS

V.R. FERRIS, Purdue University, School of Agriculture, *Lafayette, Indiana* 47907

The goal of the proposed research is to develop methods for sampling and analyzing nematode populations from water resource areas of known contrasting conditions, in order to establish baselines and indices by which this group of aquatic organisms may be used as a tool for quantifying ecological change. Benthic and shoreline samples will be taken from specified areas where the streams are used to dispose of waste materials. Detailed ecological data will be recorded, including physical and chemical characteristics of soil and water in the areas. Permanent mounts of nematodes recovered will be prepared. Nematode populations will be analyzed, and curves constructed to express community structure in the various sites studied. Importance values will be calculated for each species based on frequency and density values and on a metabolic factor for each species. Matrices will be constructed to show coefficients of similarity and dissimilarity for each of the sampling sites and diversity indices calculated. Ordination constellations will be constructed.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0585, PREIMPOUNDMENT STUDY OF WATER QUALITY, SAYLORVILLE RESERVOIR DES MOINES RIVER, IOWA

E.R. BAUMANN, Iowa State University, School of Engineering, *Ames, Iowa* 50010

Several large reservoirs are under construction in Iowa by the U.S. Army, Corps of Engineers. Water quality in reservoirs in the northern plains states is of increasing concern, especially in view of potential downstream water uses, water quality requirements, and reservoir recreation demands. A three-year preimpoundment study was initiated in 1967 to measure selected water quality parameters in the area of Saylorville Reservoir. This reservoir is located on the Des Moines River north of Des Moines, Iowa and extends 50 miles upstream to Boone, Iowa.

Measurements and samples are being taken weekly at five stations in the reservoir area under natural river conditions prior to completion of the dam. A continuous water quality monitoring station will be located at one station to provide continuous records. Parameters of water quality included in the study are: temperature, turbidity, pH, chemical oxygen demand, biological oxygen demand, dissolved oxygen, carbon dioxide, chlorophyll, phosphates and all forms of nitrogen. Additional parameters are analyzed periodically and diurnal studies also performed.

The study is being made to determine the type and nature of the aquatic environment which exists under natural river conditions and provide data which can be used later in comparison with post-impoundment conditions.

SUPPORTED BY Iowa State University

2.0586, MOLECULAR AND APPLIED ASPECTS OF MICROBIAL ENZYMOLOGY AND ECOLOGY

P.A. HARTMAN, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01763)

OBJECTIVE: Investigate: the use of enterococci as indicators of fecal pollution of water and foods. The genetics, regulation, production, purification, properties, and applications of bacterial amylases.

APPROACH: Physiological and gas chromatographic data of possible use in differentiation of enterococci will be examined and attempts made to develop improved media and methods for isolation and enumeration of enterococci; these will be used to study the ecology of enterococci. Amylase isoenzymes will be isolated and compared with other bacterial amylases, the genetics, regulation and excretion of amylases will be examined; and applications sought.

PROGRESS: (a) Enterococci - 29 streptococci (including 17 enterococci) were exposed to 30 different tests; 11 tests were evaluated further using fresh isolates; 9 tests were found that might have value in differentiating plant from animal types. Preliminary gas chromatographic fatty acid analyses also were made. (b) Amylases - Mutants of B. subtilis blocked in cell-wall synthesis have been isolated; from these we hope to obtain doubly-blocked mutants that can be used to study mechanisms of amylase excretion. Expected linkage of amylase (amy) genes of B. subtilis to Group IV markers was not realized; linkage to markers within the other 3 groups have been studied superficially and will be studied in greater detail. Mutations in control or level of amylase production also have been isolated and partially characterized. Slide electrophoresis of our amylases is being perfected. (c) Immune reactions in insects - Tenebrio and Galleria larvae were used to examine immune responses in invertebrates. Tenebrio did not exhibit a response to MS-2 phage or Ps. aeruginosa bacterins. The phage did not immunize Galleria; the bacterin was toxic to some Galleria lines. Mechanisms of toxicity were examined. (d) A new immunological template model is being developed. The model, in its present form, accomodates existing data more readily than does any model heretofore proposed.

SUPPORTED BY Iowa State Government - Des Moines

2.0587, QUALITY OF TILE EFFLUENT

H.P. JOHNSON, Iowa State University, Agricultural Experiment Sta., *Ames, Iowa* 50010 (IOW01805)

OBJECTIVE: Determine plant nutrients content (N,P,K) of effluent from tile outlet terraces and from subsurface drainage systems under row crop. Investigate the mechanics of NO(3) movement in water-saturated and -unsaturated soil by miscible displacement experiments.

APPROACH: Field work, Part one: Sample soil and water discharged from tile outlet terraced area under fertilized corn or beans. Analyze water and soil for N, P and K and compute nutrient losses involved. Part two: Sample effluent from subsurface drainage system under row crop. Analyze for N, P and K and compute total nutrient losses from effluent. Laboratory work: add saturated phosphorus solutions to soil columns; plot concentration of phosphorus in effluent with time and compare with rate of addition of phosphorus. Study distribution of phosphorus in columns after completion of experiment.

PROGRESS: A Hach Chemical Company method for testing for phosphorous has been tested. In this method the phosphorous determination depends on transmittance of light through a phosphorous solution to a photocell. It was therefore found important to filter particles from the leaching water before phosphorous tests were run. The method was used to determine phosphorous leached from laboratory soil columns of topsoil. Concentrations ranged from about 0.05 to 1.00 microgram of elemental phosphorous per milliliter of water. Surface water running from the plow layer through large root holes and cracks in soil to tile drains might be expected to reach these concentrations. In soil without large channels, it is believed that the phosphorous almost totally absorbed before reaching the tile. Two automatic tile effluent samples have been obtained. Plans are proceeding for measuring nutrients discharged with tile effluent. The effluent from tile outlet terraces was collected and analyzed (Coop with ARS) for N, P and K. A thesis which defines the effect of diking and straightening a stream (Boyer River) was completed. Flood peaks have been increased about three times and duration of overbank flow from three to five times. Tile and surface drainage experiments were continued.

SUPPORTED BY U.S. Dept. of Agriculture

2.0588, DEMONSTRATING THE ELECTROLYSIS BOD MEASURING METHOD

J.C. YOUNG, Iowa State University, School of Engineering, *Ames, Iowa* 50010

The electrolysis BOD system provides a method of continuously and automatically recording the oxygen uptake of polluted waters. In principle, the system is an automatically adjusting respirometer in which the pressure adjustment is made by replenishing the depleted oxygen supply with oxygen produced by electrolysis of the water in a weak electrolyte solution. The proposed research involves placing electrolysis BOD systems in a number of wastewater treatment plants within the State of Iowa where they will be operated by plant personnel. The systems will be used to measure the BOD at various points within the plants. The principle objectives of the study are 1) to demonstrate the advantages of the electrolysis system when used for actual plant operation purposes, and 2) to obtain BOD data from several types of treatment plants. The data will in turn be used to evaluate the performance of the individual types of plants and to investigate the possibility of using oxygen uptake rate as a parameter in designing such plants.

Results obtained in the first year of the project indicate that the electrolysis system is extremely valuable for studying the biodegradability of industrial wastes since the system can be operated for weeks or months without depleting the oxygen supply within the reaction vessel. One of the most significant findings is that the first-order reaction rate coefficient for domestic wastewaters is two to three times higher than reported from dilution BOD methods.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0589, COLIBACTERIOPHAGES AS VIRUS INDICATORS IN WATER AND WASTEWATER
Y. KOTT, Technion, *Haifa, Israel*

Due to the potential danger of transmission of enteroviral diseases by the water route, and in some instances, the low reliability of the coliform index, a more suitable indicator is required in water quality control. E. coli bacteriophages are proposed to be used as the new indicator.

The proposed phases of investigation are: a. To establish a phage enterovirus ratio, applicable to any water body. b. To use this new indicator for developing criteria for the colibacteriophages pollution index.

The bacteriophages have been chosen because of their fecal origin, specificity of attachment to bacteria, short generation time, high multiplication rate and resistance to chemical agents.

The current directions of research are: 1. Isolation of E. coli bacteriophages. - In order to be able to identify the E. coli strains of bacteria, more than 70 colibacteriophages have been isolated and tested on a few hundred E. coli strains isolated from water. 2. A number of specific Aerobacter aerogenes bacteriophages have been isolated and identified. The electron micrographs showed their heads and tails to be of various sizes and lengths. 3. With the aid of these colibacteriophages a test has been devised in which a given sample of water was filtered through a Membrane Filter, exposed to specific colibacteriophages and subsequently incubated on a differential medium. Results were recorded after 18-24 hours and field tests are planned. 4. The recovery of coliphages filtered through Membrane Filter was 100 per cent when the filter was pre-treated with serum. Field samples also showed good results.

2.0590, PARTITION COEFFICIENTS FOR FE, MN, CO, NI, ZN, CU, BETWEEN RIVER WATER AND SUSPENDED LOAD
E.E. ANGINO, Univ. of Kansas, School of Engineering, *Lawrence, Kansas* 66044

The study of selected heavy metal (Fe, Mn, Ni, Co, Cu, Zn) partition coefficients between the suspended and dissolved load of streams and the relation to the mineralogical make-up of the suspended load will be investigated. The trace element chemistry will also provide background and seasonal values for the streams in question. Such data is needed if we are ever to be able to establish water quality standards for the metals in question. It is hoped that this study can shed some light on the effect of the suspended load on the water quality and chemistry of the dissolved load of streams under natural conditions. Each sample from the stations and river systems mentioned in the proposal will also be studied for the chemical parameters noted, mineralogic make-up and their relation to the geology of the terrain over which the streams flow.

2.0591, APPLICATION OF ELECTRON SPIN RESONANCE IN WATER POLLUTION STUDIES
E.E. ANGINO, Univ. of Kansas, State Geological Survey, *Lawrence, Kansas* 66044

Many of the problems involved in water pollution are affected by the non-equilibrium systems prevailing in natural systems. To know what some of the heavy metal species present in aqueous solution is of interest. Theoretically, Electron Spin Resonance is a possible tool for studies of this type. However, it has not been evaluated for this application. Starting with Fe, Mn, Cu, and Cr solutions of different pH and species, the change in oxidation state will be followed by use of ESR recordings.

Significant changes in the ESR patterns for each species (as a function of pH) should provide a means of monitoring similar chemical changes in natural water systems. This possibility will be checked against samples from known water pollution systems (urban such as urban drainage ditches, rivers, reservoirs, etc.). Positive results could lead to use of ESR in continuous monitoring systems for water pollution.

2.0592, THE EFFECT OF URBANIZATION ON SMALL DRAINAGE BASINS
P.L. HILPMAN, Univ. of Kansas, State Geological Survey, *Lawrence, Kansas* 66044

To investigate the physical and biological changes in small drainage basins brought about by the transition from rural to urban land use.

The initial phase of the project will consist of a complete survey of the geological, zoological and botanical conditions of a small (4- square-mile) rural drainage basin adjacent to a rapidly expanding urban area. After completion of the survey the drainage basin will be re- evaluated on an annual basis over a 4- to 5-year period in an attempt to correlate changes noted with increasing urban influence. Meteorological and hydrological data will be recorded continually throughout the study period. Subprograms of the project include: (1) effects of urbanization on quality and quantity of runoff; (2) usefulness of farm ponds as indicators of antecedent climatological conditions in drainage basin studies; (3) the effect of modifications of vegetation, slope and soil on runoff; (4) the influence of directional storms on hydrographs in small drainage basins; (5) assets and liabilities of upland waste-disposal sites and their relationships to surface and subsurface water quality; (6) the usefulness of analog and digital modeling techniques in predicting the effects of urbanization on drainage-basin performance; (7) the usefulness of remote-sensing devices in drainage-basin studies; and (8) the value of drainage-basin analyses in land-use planning.

2.0593, MULTISPECTRAL CAMERA CLUSTER
R.K. MOORE, Univ. of Kansas, Ctr. for Res., *Lawrence, Kansas* 66044

A four-camera multispectral cluster using 70 mm Hasselblad cameras is being acquired for use in earth observations research at the University of Kansas. The camera cluster will be mounted on the University aircraft and will be available for various projects. Availability of the IDECS (Image Discrimination and Enhancement Combination System) developed under NASA and DOD sponsorship will permit studies of automated analysis of the multispectral photos resulting from the camera cluster. Use of the instrument is expected in on-going projects involving studies of crop identification and stress, range lands, urban land use, transportation networks, hydrology and water pollution, ecology of natural plant communities and archaeology.

SUPPORTED BY U.S. Natl. Aero. & Space Adm.

2.0594, WATER QUALITY MODELING AND PREDICTION
E.S. LEE, Kansas State University, School of Engineering, *Manhattan, Kansas* 66502

The primary objective of this research is to apply the recently developed modeling and prediction techniques such as the quasilinearization technique, invariant imbedding, and nonlinear filtering and estimation to establish realistic mathematical models. It will be shown that by the use of these modeling techniques, computational requirements can be reduced and certain experimental difficulties in obtaining the data can be eliminated.

Another objective of this study is to develop and improve the above mentioned techniques for water quality modeling. Since all the modeling techniques to be used are fairly new, further developments and improvements which are especially suited for water quality modeling will be made.

The modeling and parameter estimation of (1) the amount of pollutants in a water stream or river with and without longitudinal dispersion, (2) the estimation of rate constants in waste treatment systems, and (3) dynamic modeling will be studied. Only plug flow situation will be studied in the dynamic modeling.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0595, INTERACTIONS OF MERCURY WITH AQUATIC AND EDAPHIC ENVIRONMENTS

G.M. PAULSEN, Kansas State University, School of Agriculture, *Manhattan, Kansas* 66502

Physicochemical and biological interactions between mercury and its environment are determined to predict pollution, distribution, and effect of mercury on aquatic colloids, alluvium, and flora. Physicochemical constants measured using 203 Hg-labeled methylmercury chloride and mercuric chloride, aquatic colloids, and three aquatic alluvium types include distribution, diffusion, and activity coefficients; cation exchange capacity; and retention and elution by leaching columns. Effects of varied mercury concentration and colloidal and alluvial pH will also be measured. Using Lemna app. as representative aquatic flora, effects of methylmercury chloride and mercuric chloride on mercury adsorption and accumulation, growth, photosynthesis, and aquatic oxygen concentrations will be determined. Treatment variables for Lemna are autotrophic and heterotrophic conditions, three mercury concentrations, three aquatic temperatures and, under autotrophic conditions, two light intensities.

2.0596, THE ECOLOGY OF DRAKE'S CREEK, KENTUCKY

R.D. HOYT, Western Kentucky University, School of Science, *Bowling Green, Kentucky* 42101

General objectives: 1. The training of individuals (graduate students) in the procedures of aquatic biological research, data analysis, and interpretation. 2. The establishment of 'baseline' limnological characteristics of regional aquatic environments as the basis for their management under increasing pressures of industrialization and urbanization in the future.

Scientific objectives: 1. A general survey of the flora and fauna establishing qualitative aspects of the communities as they presently exist. 2. The identification and subsequent study of ecological problems involving specific components of the flora and fauna.

SUPPORTED BY Lenk Manufacturing Co. - Franklin, Ky.

2.0597, INFLUENCE OF THE EFFLUENT FROM A CONCENTRATED INDUSTRIAL COMPLEX ON A LARGE RIVER - EFFECTS ON INDICATOR ORGANISMS

H.M. HANCOCK, State Dept. of Fish & Wl. Rso., *Frankfort, Kentucky* 40601

Objectives. To determine what happens to indicator organisms held in control and affected areas.

Procedures. Artificial substrates will be placed in various places in the river. Sample bottom material and test organisms (corbicula and insect larvae) will be placed in the one cu. foot openings in 260 lb. cast concrete artificial substrates. They will be kept in place with hardware cloth. The substrates there will be placed in control and influenced areas and left for various intervals. Organisms will be examined for physical appearance, and then some organisms and some muds will be returned to be tested for inorganic and organic constituents as previously described. Newly trapped micro and macro benthos will be determined in the laboratory. Approximately 538 hours for chemical consultation and 435 hours biological consultation will be required for this job.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish

2.0598, ANALYSIS OF SOLUTIONS FOR SURFACE-ACTIVE CONSTITUENTS

H.H. BAUER, Univ. of Kentucky, Water Resources Institute, *Lexington, Kentucky* 40506

The behavior of surface-active substances at electrodes will be investigated in order to identify the effects due to the nature of the surfactant, the nature of the electrolytes present, and the relation between these two factors at different concentrations of both types of substances. These studies will be made by the tensammetric method which is well established.

The results will indicate the extent to which such methods can serve for the determination of surfactuants in the presence of the wide variety of other substances that one expects to be present in samples of water that will need to be monitored for possible pollution. In addition, it may become possible to treat adsorption processes on a theoretical basis that includes the effect of the presence of electrolytes at the surface; present theories do not take this effect into account.

The applicability of a new technique of greater sensitivity and precision than the tensammetric method will be explored after the main features of the phenomena occurring have been elucidated by the tensammetric technique.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0599, DETECTION AND IDENTIFICATION OF MOLECULAR WATER POLLUTANTS BY LASER RAMAN SPECTROSCOPY

E.B. BRADLEY, Univ. of Kentucky, Water Resources Institute, *Lexington, Kentucky* 40506

The proposed research is a study of the application of laser Raman spectroscopy in the detection and identification of molecular water pollutants. The primary advantages in such an approach are (1) laser Raman spectroscopy offers a direct method of detection and identification of molecules in water solution or suspension, and (2) the ability to detect and identify high-molecular-weight pollutants.

Laboratory and field investigations will include the following: (a) preparation of standard samples of various industrial and agricultural molecular water pollutants to which Raman spectroscopy is uniquely applicable, (b) use to standard samples to establish levels of detectability, sensitivity limits, and numbers of compounds in representative polluted water samples from industrial effluents that can feasibly be detected and identified by laser Raman spectroscopy at one time without separation techniques, (c) construction and testing of internal-beam-condensing cells, multiple-entrance cells, and laser- cavity cells, (d) sensititivity enhancement of Raman spectra by beam ratioing, (e) development of a catalog of standardized Raman spectra of a wide variety of water-soluble industrial waste products divided into the following categories: 1. organic pesticides, 2. petroleum products, 3. detergents, 4. inorganics.

The data will be employed to develop practical applications of laser Raman spectroscopy for the extension of analytical techniques of molecular identification outside the normal capability of GLC and mass spectroscopy.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0600, TAXONOMY AND PHYSIOLOGY OF PROTOZOA IN CAVE STREAMS AND POOLS

S.M. GITTLESON, Univ. of Kentucky, Graduate School, *Lexington, Kentucky* 40506

The proposed research involves laboratory and field investigations of taxonomy and physiology of protozoa in cave streams and pools. Preliminary studies in Pine Hill Cave Kentucky indicate that: 1) numerous species of protozoa do occur in significant forms in streams and pools that sink into the cave; 3) many of these protozoa have never been described.

This data suggests that knowledge of the role of protozoa in the ecosystem is important for understanding problems concerning the ecological impact of water development, ground water purity and effects of pollution on groundwater.

Investigations primarily at the Mammoth Cave National Park, Kentucky, will include study of samples from cave streams, pools and surface water related to: 1) identification of protozoa; 2) distribution of protozoa; 3) chemical analysis (ions, gases, total inorganic and organic carbon) and physical analysis (temperature, conductivity, viscosity; specific gravity) of the water; and 4) study of how peculiar conditions of caves - low temperature and absence of light effects type, number, survival, growth and motile behavior of protozoa.

2. WATER QUALITY

SUPPORTED BY University of Kentucky

2.0601, DIGITAL COMPUTER MODELING OF LIMESTONE GROUNDWATER SYSTEMS
J. THRAILKILL, Univ. of Kentucky, Graduate School, *Lexington, Kentucky* 40506

Digital computer techniques to model limestone groundwater basins in two and three dimensions will be developed. Finite difference, finite element, and pipe network flownets will be investigated, and both darcy and turbulent flow cases will be studied. Emphasis will be on evolution of the aquifer in response to geologic controls, including geochemical parameters (state of saturation of recharge to the aquifer). Models will be created for the Mammoth-Cave-Sinkhole Plain aquifer in Kentucky and other ground-water systems.

Application of the models will be to further understanding of the nature and development of limestone aquifers and to furnish predictive information, including well siting and pollution paths, for specific ground-water basins.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0602, WATER RESOURCES OF THE BOWLING GREEN AREA, KENTUCKY
T.W. LAMBERT, U.S. Dept. of the Interior, Geological Survey, *Louisville, Kentucky* 40202

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of Kentucky.

Purpose: To provide information on the quantity and quality of the water in the Bowling Green area for use in planning additional industrial development.

Methods: Detailed information on ground-water sources will be collected with particular emphasis on delineating the areas of potentially high yield. The investigation will include a study of the underground flow patterns and potential sources of contamination. Information on water quality of streams and aquifers will be collected and changes in water quality monitored. The relationship between ground water and water in streams is particularly significant because of large base flows and recurrent flooding of large solution channels by high river stages. Partial-record stations will be operated on tributary streams for correlation of record with the gaging and water quality station on Barren River at Bowling Green.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0603, THE IMPACT OF MICROORGANISMS ON OIL
S.P. MEYERS, Louisiana State University, School of Agriculture, *Baton Rouge, Louisiana* 70803

The ability of yeasts and molds to degrade a broad spectrum of organic compounds is well known, as is their ability to withstand considerable biological and abiotic environmental stress. Recent studies have shown the noteworthy hydrocarbonoclastic ability of these organisms. Significant densities of various yeast taxa in the Louisiana marshland with its vast shrimp and fish industry, suggest the need for critical evaluation of the population dynamics of these organisms under a variety of stress and oil spill conditions. Tests are proposed to evaluate hydrocarbon utilization by marine-occurring yeasts and yeast- like fungi in the shrimp-oyster region of Louisiana and to ascertain the response of these organisms to oil intrusion into the marshland rhizosphere. Response of the major bacterial population will be evaluated in terms of the hydrocarbonoclastic yeast concentration. Dominant hydrocarbonoclastic species will be evaluated as possible bioassay organisms of levels of petroleum contamination. Attention will be given to ultimate development of techniques for accelerated biodegradation of oil pollutants in such aquatic habitats.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.0604, SEDIMENTOLOGY OF LOUISIANA'S ESTUARIES
W.S. PERRET, State Wildlife & Fish Comm., *New Orleans, Louisiana* 70130

Objectives: (1) To determine the sediment forms of the state estuaries as an index of their respective condition. (2) To determine the degree to which alterations have already affected sediments and to establish a base line for the evaluation of future estuarine modifications, their effect on sediments, and subsequently in the biota. (3) To develop data for the sedimentology of the estuaries of La. to be available for inclusion in an atlas of the Gulf of Mexico estuaries in cooperation with the other states of the Gulf States Marine Fisheries Comm. and the Bureau of Comm. Fisheries.

Procedures: Data will be obtained for textural analysis (sand, silt and clay) and, if feasible, carbonate, carbon and nitrogen content of the sediments in the study areas. Sufficient samples will be collected to present a complete picture of the sediment characteristics of the study areas. Samples will be collected by means of a dredge or grab sampler. All data will be collected, analyzed and prepared in a form which will be available and acceptable for incorporation as a section in an atlas of the estuaries of the Gulf States according to the techniques and procedures recommended by the Estuarine Technical Coordinating Committee of the Gulf States Marine Fisheries Commission.

Part 3 of 4.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.0605, DISPOSAL OF PAPER MILL EFFLUENT THROUGH IRRIGATION OF BOTTOMLAND HARDWOOD UNDER LOUISIANA CONDITIONS
C.W. WILSON, Louisiana Technological Univ., School of Agriculture, *Ruston, Louisiana* 71270

The objective of the proposed research is to determine the economic and technical feasibility of disposing of paper mill waste through irrigation of hardwood forests under Louisiana conditions.

A system for delivery of the waste water to the forest area to be irrigated will be designed. The probable increase in timber yeild from irrigation will be determined. The waste water, stream conditions, and forest conditions will be studied. From this information, economic and technical feasibility will be determined. The effect of diverting paper mill waste water on water quality of Dugdemona River will be predicted.

The results of this study should be applicable to other waste water supplies in Louisiana.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0606, PHYSICAL AND CHEMICAL CHARACTERISTICS OF MAINE STREAMS AND RIVERS
L. BOND, State Dept. of In. Fish & Game, *Augusta, Maine* 04330

Objectives: To obtain the following information on each stream investigated in order to determine its suitability as a residence nursery or spawning area for fish populations. 1. Volume of flow in cubic feet per second. 2. Length, surveyed, average width, and depth. 3. An evaluation of pools, riffles, and bottom types. 4. An evaluation of natural and man-made obstructions to fish migration. 5. Temperatures at time of survey and other periods when possible. 6. Source, type, and extent of water pollution, and oxygen determinations in critical situations.

Procedure: The brook, stream or river will be surveyed by boat or on foot to determine the extent and character of pools and riffles. Suitability as a spawning and nursery area for salmonid fishes will be determined, on the basis of volume of flow temperature, suitable bottom material, riffles, pools, and other species present.

Obstructions will be surveyed to determine their effect on migration and stream flow. Temperatures will be taken at various points along a stream to determine the effect of spring seepage, tributaries, and impoundments. The source, type and extent of domestic and industrial pollution will be determined. When critical conditions are apparent dissolved oxygen will be determined by the Winkler method.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0607, HYDROGRAPHY OF THE PENOBSCOT RIVER ESTUARY
R.W. HATCH, Univ. of Maine, Graduate School, *Orono, Maine* 04473

A long range program of studies on the ecology of the Penobscot estuary has been established by the Maine Cooperative Fishery Unit. Part I involves a detailed study of the hydrography of 30 miles of estuary from Bangor Dam to Belfast. Salinity, temperature, density and dissolved oxygen have been and will continue to be monitored with the view toward detecting changes in the estuarine environment from anticipated pollution abatement in Penobscot River. This project was initiated July, 1963.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0608, GEOCHEMICAL CYCLES INVOLVING FLORA, LAKE WATERS, AND BOTTOM SEDIMENTS
S.A. NORTON, Univ. of Maine, School of Arts, *Orono, Maine* 04473

The study is investigating variations of silica concentration in time and space in Chalk Pond - near Beddington, Maine. Critical parameters include (1) abundance and diversity of diatoms, (2) sympathetic variations in silica, sodium, potassium, calcium, iron, and aluminum ions, (3) oxidation potential, (4) acidity, (5) temperature, and (6) the mineralogy of the lake-sediment interface.

Relevance of the study to socio-economic problems is contained in the fact that diatoms constitute both a water use problem, in some lakes, and provide, generally, a useful index to conditions in the geochemical and biological cycles within the lake environment.

Suitable transect lines and sampling sites have been established to lake morphometry and field sampling of bottom sediments and water for inorganic determinations commenced in 1969. Changes in the silica regime at the time of fall overturn have been established.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0609, HYDROGRAPHIC AND BIOLOGICAL SURVEY OF MONTSWEAG BAY AND VICINITY
D. DEAN, Univ. of Maine, Ira C. Darling Ctr. for Res., *Walpole, Maine* 04573

An 850,000 KW nuclear-powered electric generating facility is under construction at Bailey Point, Montsweag Bay, Lincoln County, Maine. Initial operation is scheduled for 1 January 1972. The project is designed to establish ecological baselines for the unaltered environment prior to this date, and to assess the effects of thermal alteration thereafter.

Monitored at frequent intervals throughout the year are: temperature, salinity, nutrient levels, phytoplankton, zooplankton, benthic communities, attached algae, and fishes. Stocks of commercially important shellfish and sea worms are assessed quarterly. Sediment distribution, current patterns, and rates of sedimentation are also being studied.

SUPPORTED BY Maine Yankee Atomic Power Company

2.0610, TO DETERMINE THE PROPERTIES OF THE SUSPENDED SEDIMENT POPULATION OF CHESAPEAKE BAY
J.H. MANNING, State Dept. of Ches. Bay Affrs., *Annapolis, Maryland* 21404

The objectives of this study are to determine the properties of the suspended sediment population of the Chesapeake Bay. The area of investigation will extend from the head of the Bay at Turkey Point (and in the mouth of the Susquehanna River) to the mouth of the Bay at the Virginia Capes. The following properties will be determined: (1) the spatial and temporal variations of the concentration of total suspended solids, (2) the spatial and temporal variations of the particle size distributions (both number and volume) of the suspended solids, (3) the percent of the total suspended solids accounted for by organic matter, (4) the mineralogic composition of the inorganic fraction, (5) the relative contributions to the suspended load by river flow, shore erosion, primary productivity, and by the resuspension of bottom sediments, and (6) the fraction of suspended sediment which escapes the Bay.

Samples will be collected monthly from five or more depths at each of 18 to 20 channel stations extending the full length of the Bay. The concentrations will be determined by filtration; the percent organic matter by combustion; the mineralogy by x-ray diffraction; and the size distribution with a Zeiss Particle Size Analyzer and a Mine Safety Appliance Particle Size Analyser. These properties will be used to estimate the relative contribution by the various sources of suspended sediment.

Part 3 of 4.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.0611, TIME-OF-TRAVEL - PRINCIPAL MARYLAND STREAMS
K.R. TAYLOR, U.S. Dept. of the Interior, Geological Survey, *Baltimore, Maryland* 21204

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of Maryland.

Purpose: To provide water users a time-of-travel guide which would tell them when a contaminant would reach their intakes, how long it would persist, and what the levels of concentration would be.

Methods: A fluorescent dye will be introduced into selected streams. The time of arrival of the leading edge, the maximum concentration, and the time of passage will be measured at successive downstream locations. By several such determinations at selected rates of discharge, a relationship between discharge and time-of-travel can be developed for each reach.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0612, AUTOMATED DETERMINATION OF PRIMARY PRODUCTIVITY
G.E. LEVIN, Biospherics Research Inc., *Rockville, Maryland* 20853

The primary productivity project encompasses the development and fabrication of an automated device to determine primary productivity (the rate at which carbon is photosynthetically fixed to start the aquatic food chain) of lakes and sea by the radiocarbon technique. Biological and engineering studies have led to the conceptual design of an instrument which collects a sample of sea water in situ, delivers it to an aliguot of carbon-14 tagged sodium carbonate, incubates the sample under ambient light and temperature conditions, filters and dries the sample, and then measures the metabolically incorporated radioactivity with a GM counter. Some of the proposed applications are: (1) As a monitor to record the productivity before, during and after the addition of heated water effluents into a bay. This should permit direct measurements and provide historical and factual data on the effects of thermal discharges. (2) As an analyzer for destratification studies in a large impoundment where the traveling sampler could move up and down the fixed buoy cable through the termocline, providing records of the effects of prolonged stratification as well as destratification on the primary productivity. (3) As an automatic monitor to determine fate of pollutants in inland surface waters. The objective is development of mathematical models to predict the water quality at various locations in stream and lake systems. One of the very important inputs, both as a source and as a sink for organics and inorganics, into such a model is the primary productivity factor. This will require the measurement of values in the field, in many locations, in order to verify the model; and automatic measurements are considered a necessity. (4) As a short- term analyzer in research cribs to be set up in estuarine waters. A number of adjacent cribs will be established by dropping plastic curtains in water bodies, adding selected materials in various combinations and amounts, and measuring the primary productivity that occurs within the periods.

This project is being conducted in close collaboration with FWPCA.

SUPPORTED BY U.S. Atomic Energy Commission

2.0613, ASSAYS OF TOXIC POLLUTANTS BY FISH BLOOD ABERRATIONS
W.A. CURBY, Lahey Clinic Foundation Inc., *Boston, Massachusetts* 02215

We have developed a biological multichannel analyzer which, using a sensor that operates on the Coulter principle, measures and distribute mixed cell populations by cell size. It provides an analog distribution, a digital printed readout and a binary coded decimal magnetic tape recording for future analysis. Although primarily a pulse height analyzer (applied successfully to studying e.g. bacteria, mammalian blood, inert dusts), it operates as a pulse shape analyzer if the instant at which each pulse height is read is varied. This technique, applied to whole blood from freshly sacrificed Fundulus heteroclitus shows the alterations with time and the variations caused by traces of cadmium and copper in the aquatic environment for 24 hours. The size frequency distribution patterns of each trace element environment differ from each other, and each, markedly from the norm.

We propose to investigate and record the response of Fundulus whole blood cells from fishes living in several aquatic environments of fixed pH and dissolved oxygen contents and temperature at varying intervals of time. We will then compare these data with those which we will obtain from fish subjected in similar environments to dissolved traces of chemical pollutants. We know that blood cell changes do occur and that we can measure them. Our objective is to determine the limits of several types of toxic pollutants.

This work will be performed in the Biophysics Research Laboratories of the Brooks Hospital Division of the Lahey Clinic Foundation at 211 Summit Avenue, Brookline, Mass. 02146.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0614, ASSAYS OF TOXIC POLLUTANTS BY FISH BLOOD ABERRATIONS
W.A. CURBY, Lahey Foundation, *Boston, Massachusetts*

2.0616, ANALYSIS OF MERCURY CONTENT OF SHELLFISH OFF THE MASSACHUSETTS SEACOAST
C.M. JANKOWSKI, Northeastern University, Graduate School, *Boston, Massachusetts* 02115

An initial survey is being made of the mercury uptake by shellfish in polluted coastal waters. Concurrently analysis methods are being developed and compared. Primary emphasis is on atomic absorption and spectrophotometric procedures.

SUPPORTED BY Northeastern University

2.0617, ANALYSIS OF FISH TISSUE FOR MERCURY CONTENT
T. PALERMO, State Div. of Fisheries & Game, *Boston, Massachusetts* 02202

Objectives: To determine if mercury, a problem environmental contaminant, is present in fish from Massachusetts waters.

Procedures: Fish collected statewide during the course of regular fish population sampling activities from the Connecticut, Merrimack and Housatonic Rivers along with fish collected specifically for this purpose from the Millers, Westfield, Deerfield, Nashua, Squannacook, Taunton and Blackstone Rivers will be analyzed for mercury content. The analytical procedure will be as described by Berman, Determination of Cadmium, Thallium and Mercury in Biological Materials by Atomic Absorption, Atomic Absorption Newsletter, Vol. 6, No. 3, May-June 1967.

A Perkin-Elmer, Model 303 Atomic Absorption Spectrophotometer, equipped with a hollow cathode mercury lamp will be used for analysis. If mercury content is found in the above-named river systems, then this job will be expanded.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0618, SHELLFISH TECHNICAL ASSISTANCE
H.A. CARR, State Div. of Marine Fisheries, *Boston, Massachusetts* 02202

Objectives: To provide technical assistance to shellfish officers, town officials and shellfishermen in regard to the regulation and management of the shellfish resources. To provide technical assistance in regard to techniques of modern culture and harvesting of important shellfish found along the coast of Massachusetts. To encourage regional cooperation and planning, and to educate those involved in the fishery by publishing informational material on the shellfish resource and making it available to local interests.

Procedures: Assistance will be given in regard to the regulation of fishing pressure, opening and closing of areas, catch limits, methods of harvesting, etc. Project personnel will also attempt to provide assistance on effective control of shellfish diseases, predation, pollution, and coastal alteration projects that would involve marsh and flat destruction. To aid this program, the effects of introduced pollutants on or near shellfish areas will be monitored. Technical assistance will be given for the modern techniques of shellfish propagation, especially with the oyster, quahog, and soft-shell clam resources. Techniques in oyster propagation will involve the construction of oyster rafts, the use and distribution of cultch, and the promotion of the grant system. The quahog and soft-shell clam resource will involve assistance towards better transplanting techniques and the use of more efficient harvesting equipment. To promote regional cooperation and planning by encouraging cooperative management and harvesting in common shellfish areas; oyster spat collection and distribution; relaying quahogs, soft-shell clams, and bay scallops. Information will be available as to the possible sources for shellfish seed stock.

2.0619, OPTIMUM LINEAR SYNTHESIS IN URBAN HYDROLOGY, PHASE II
P.S. EAGLESON, Mass. Inst. of Technology, School of Engineering, *Cambridge, Massachusetts* 02139 (C-1706)

The goal of this research is to develop and evaluate a new method for the prediction of the entire hydrograph of surface runoff given the time-distribution of rainfall excess. The method is to have an accuracy and to involve a computational effort which are compatible with its incorporation into algorithms for the optimal design of urban drainage systems.

Development of the method will involve systematic investigation of the errors introduced into analytical models of surface runoff systems by linearization and by lumping of systems which are inherently distributed and non-linear. These aspects of the research results will be of equal value in the development of improved analytical models for forecasting the surface runoff component of streamflow in rural areas also.

2.0620, A STUDY PROGRAM TO IDENTIFY PROBLEMS RELATED TO OCEANIC ENVIRONMENTAL QUALITY - NORTH ATLANTIC
V.T. BOWEN, Woods Hole Oceanographic Inst., *Woods Hole, Massachusetts* 02543

This project to identify the major problems of man's contamination of the oceans will be carried out in two parts; (1) Samples of the ocean environment including zooplankton, fishes (migratory and non- migratory), benthic organisms sediments, sea water, surface slicks, and airborne material will be analyzed for pollutants (heavy metals, transition metals, pesticides, and petroleum derived hydrocarbons). (2) Following completion of the above program, a study group will be convened in Woods Hole to discuss the results and to interpret them. The final product will be the planning document for a full-scale research program in the Environmental Quality of the North Atlantic Ocean. Woods Hole Oceanographic Institution will provide the large ship sampling effort; chemical analyses of pesticides and petroleum derived hydrocarbons; will ensure intercalibration of the United States and United Kingdom laboratories; and will host the study group responsible for interpreting the results of the baseline study and recommending a course of action for Environmental Quality research in the North Atlantic.

SUPPORTED BY U.S. National Science Foundation

2.0621, GEOSECS - PREPARATIONS R/V KNORR, CONSTRUCTION GEOSECS BUILDING, PROVISION SHIPBOARD EQUIPMENT, AND THE GEOSECS SUMMER INSTITUTES
J.M. HUNT, Woods Hole Oceanographic Inst., *Woods Hole, Massachusetts* 02543

Considering the ocean as a source of food, a disposal area for nuclear and industrial waste products, and a controlling factor in the earth's climatic regime, our ultimate use of the sea is critically dependent on a detailed understanding of processes presently understood in only the vaguest and most qualitative way. These are the stirring and mixing processes in the deep sea, the interchange of material between deep and surface water, the variation of organic productivity throughout the ocean, and the exchange of water and gases with the atmosphere. The GEOSECS program will measure in detail the oceanic constituents along the Arctic to Antarctic sections at all depths, to provide, for the first time, a set of physical and chemical parameters measured on the same water samples. These data will provide the input for quantitative studies of oceanic mixing and organic productivity, and, at the same time, serve as a baseline for the levels of pollutants and of fission and waste products being added to the sea. Woods Hole Oceanographic Institution will prepare and provide R/V KNORR for the first Atlantic cruise logistic support and facilities for shipment of equipment, samples and personnel, provide a collection and distribution center for samples for shore analysis, establish and maintain a 'water library', provide sampling equipment, equipment for shipboard processing for trace elements and particulates, and a series of lectures, discussions and work shops on ocean modeling.

SUPPORTED BY U.S. National Science Foundation

2.0622, MICROBIAL TRANSFORMATIONS IN SEA WATER
H.W. JANNASCH, Woods Hole Oceanographic Inst., *Woods Hole, Massachusetts* 02543

Funds from this grant continue support by the National Science Foundation of investigations of microbial transformations in seawater. The present research has three major aspects: 1) the experimental measurement, by a newly developed technique, of growth rates of marine bacteria isolated from different types of seawater; 2) direct studies of microbial activities by in situ experiments; and 3) the use of pressurized vessels for taking samples and for culturing bacteria for laboratory experiments which eliminate problems caused by sample decompression. These investigations of the microbes of deep sea environments, which serve as the ultimate place of collection of inorganic and organic waste materials, will provide information necessary to our knowledge of the types of organisms which live on the variety of substrates encountered in various oceanic environments. Such information is also needed in order to make knowledgeable decisions concerning off-shore dumping of waste products.

SUPPORTED BY U.S. National Science Foundation

2.0623, WATER QUALITY MONITORING IN DISTRIBUTION SYSTEMS
R.M. BROWN, Natl. Sanitation Foundation, *Ann Arbor, Michigan*

The overall objective of this project is to develop a continuous monitoring system for use in quality control of water purification processes and detection and control of water quality deterioration in distribution systems. During the first year of the project, a well equipped electroanalytical laboratory was established, and a commercially available automatic water quality data acquisition system (Schneider Instrument Model RM 25 Robot Monitor) was acquired and installed in the laboratory.

Specific ion electrode systems for the determination of (a) fluorides, (b) chlorides, (c) nitrates, and (d) hardness have been studied. The performance characteristics of these electrode systems have been established and their adaptability for use in continuous flow systems is currently being investigated. Emphasis has been placed on defining the constraints of a continuous flow system in terms of sensitivity limitations, long term stability and the effect of possible interferences.

A laboratory model of a continuous stability index monitor has been constructed and is currently on-stream. In this mode, 'Stability Index' values are being recorded continuously in terms of changes in pH as well as changes in hardness before and after the water passes through a column of calcium carbonate chips. Hardness measurements are being made with potentiometric ion selective membrane electrodes.

Anodic stripping voltammetry techniques are being investigated for the characterization of trace metals in nanogram as well as the subanogram range. Of specific interest are the measurements of traces of copper, lead, cadmium, and zinc. Preliminary data indicate the analytical feasibility of this system and its uniqueness for trace metals analysis in water supplies. A continuous flow cell is being designed for on-stream monitoring adaptation of this system.

2.0624, RESEARCH ON THE MACROBENTHOS OF THE GREAT LAKES
J.K. HILTUNEN, U.S. Dept. of Commerce, Natl. Marine Fisheries Service, *Ann Arbor, Michigan* 48107

The objective of this project is to determine the kinds of bottom dwelling macroinvertebrates and their ecology in the Great Lakes and connecting waters.

2. WATER QUALITY

Research on freshwater macrobenthos cannot only yield data on the availability of fish-food organisms but also provide insights into the relationships between species and water quality. Areas in which studies of bottom fauna are currently underway include Lakes Erie, St. Clair, and Huron. In Lake Erie and the St. Marys River benthological research is confined mostly to taxonomy and ecology of microdrile oligochaetes. Among aquatic invertebrates, populations of oligochaetes are generally the best indicators of pollution.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0625, POTENTIAL ALGAL PRODUCTIVITY AS MEASURED BY A TURBIDOSTAT
J.A. BORCHARDT, Univ. of Michigan, School of Engineering, *Ann Arbor, Michigan* 48106

This project involves the use of the principle of the turbidostat in a multiphased effort designed to give some indication as to whether this technique can yield consistent and relevant data regarding the potential algal productivity of natural waters and wastes.

The study will involve the use of this apparatus on a natural stream with a local source of pollution: the study of effluents from certain advanced waste treatment procedures and evaluating their possibilities for reducing potential productivity; the comparison of the steady state turbidostat with a batch approach to productivity; the development and evaluation of a simple package turbidostat which can be easily used by a sewage plant operator; and the development of an electronic package to monitor and control incident light.

The turbidostat has been operated quite successfully for a decade in the area of stripping nutrients from sterilized and unsterilized sewage effluent and from a variety of synthetic substrates. It would seem logical that the same type of instrument could be used as a potential algal productivity monitoring device.

SUPPORTED BY U.S. Environ. Protect. Agency - W.Q.O.

2.0626, PREDICTION OF THE MAGNITUDES AND FREQUENCIES OF FLOODS IN MICHIGAN
E.F. BRATER, Univ. of Michigan, School of Engineering, *Ann Arbor, Michigan* 48106

The influence of various rainfall and drainage basin characteristics on the magnitude and time distribution of flood runoff is being investigated on 15 drainage basins in the Detroit metropolitan area. The population of these basins varies from 60 to 7500 persons per sq. mile. The purpose of this research is to determine a better understanding of the surface runoff process with particular emphasis on the effect of urbanization. The specific practical result of the study will be the development of more accurate methods of predicting floods of various frequencies on watersheds of varying size, taking into account the effect of urbanization. This will permit more effective flood plain planning and more economical designs of storm water drainage structures.

SUPPORTED BY U.S. Dept. of Transportation - Public Rds.

2.0627, NUTRIENT ENRICHMENT AND EUTROPHICATION OF LAKE MICHIGAN
D.C. CHANDLER, Univ. of Michigan, Great Lakes Research Division, *Ann Arbor, Michigan* 48104 (AT(11-1)-2003)

Our research program on the nutrient enrichment and eutrophication of Lake Michigan has been designed to determine what specific nutrients in the Great Lakes system, particularly Lake Michigan, are important in artificial eutrophication. The research objectives are: (1) to determine limiting nutrients for phytoplankton populations. (2) To measure seasonal changes in the chemical composition of Lake Michigan waters and phytoplankton. (3) To obtain empirical relationships between chemical composition of the water and the productivity and biomass of phytoplankton. (4) To relate these data to the rate and extent of eutrophication and to identify methods of nutrient control which might be used in lake management.

SUPPORTED BY U.S. Atomic Energy Commission

2.0628, WATER QUALITY, GRAND TRAVERSE BAY, LAKE MICHIGAN
J.J. GANNON, Univ. of Michigan, School of Public Health, *Ann Arbor, Michigan* 48104

To measure the quality, quantity, and sources of microbiological contamination entering Grand Traverse Bay and to determine the behavior of those organisms between source and final point of deposit; to analyze the possibilities of remote sensing for the developmental aspect of the technique itself.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0629, ECOLOGICAL MONITORING OF STREAM SYSTEMS
F.F. HOOPER, Univ. of Michigan, School of Natural Resources, *Ann Arbor, Michigan* 48104

To investigate the feasibility of monitoring changes in stream quality using drift organisms, we plan to investigate the critical relationships between the density of benthic bottom fauna and the quantity and quality of drift. We will (1) construct 4 experimental stream channels, (2) introduce selected species of stream insects (3) vary the density of certain species among experimental and control channels and (4) measure the effects of these manipulations upon drift rate.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0630, DETECTION, IDENTIFICATION, AND DETERMINATION OF OILS, TARS, AND SLIMES BY REFLECTANCE SPECTROSCOPY
H.B. MARK, Univ. of Michigan, Graduate School, *Ann Arbor, Michigan* 48104

Application of two types of reflectance spectroscopy to the detection, identification, and quantitative determination of oils, tars, and slimes in water and sediments are being studied. A rapid, non- destructive optical technique, requiring no sample preparation whatsoever, for the identification and determination of such pollutants is described. Some example experimental applications, which demonstrate its feasibility, have been demonstrated. Using the technique of internal reflection spectroscopy, an infrared spectrum can be obtained from a sample which has been simply smeared onto an internal reflection plate, or mixed with an optically inert solid support. As no sample pretreatment is employed, the resultant spectrum is considerably more representative of the entire original sample than is one obtained by currently employed techniques which require heating, solvent extraction, etc. At present we are cataloging reference data on specific pollutants that can be measured by this method studying the various instrumental and theoretical parameters involved in order to optimize the resolution and sensitivity. We are also applying this method to sediment samples currently being taken by USC and this laboratory in a study of the Santa Barbara Channel blowout of the winter of 1969. A second technique for instantaneous detection and characterization of oily films on water surfaces, which would be suitable for continuous pollution monitering, is being built. This technique employs external (specular) reflectance from the water surface. A study of optical parameters of this system and the optimization of the design of such instrumentation is being carried out.

2.0631, REMOTE SENSING
F.C. POLCYN, Univ. of Michigan, Inst. of Science & Technology, *Ann Arbor, Michigan* 48104

To provide a multi-spectral aerial map of Grand Traverse Bay as an aid in identifying thermal plumes, pollution gradients, sediment flows, and so forth.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0632, TECHNOLOGICAL ASSESSMENT OF REMOTE SENSING
F.C. POLCYN, Univ. of Michigan, Inst. of Science & Technology, *Ann Arbor, Michigan* 48104

The investigation is designed to critically review, examine, and analyze the applicability of airborne and other remote sensing instrumentation and techniques for the detection and characterization of water pollutants in the following general categories: (a) substances floating on the water, (b) substances suspended in the water, (c) substances dissolved in the water, (d) material on the bottom of ponds, lakes and estuaries.

More specifically this study will define the capabilities of (a) operational and near operational systems, and (b) systems currently in the research and development stage to remotely characterize effluents and receiving waters in terms of water quality parameters. Additionally, this study will attempt to identify areas of research and define concepts which could lead to the development of new remote sensing systems capable of providing the physical, chemical, and biological measurements of interest in water quality management.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0633, INDICATOR PATHOGEN DENSITY RELATIONSHIPS IN TRIBUTARY STREAMS
R.J. SMITH, Univ. of Detroit, Graduate School, *Detroit, Michigan* 48221

Ratios existing between total coliforms (TC), fecal coliforms (FC), fecal streptococci (FS), and Salmonella organisms are currently being investigated in certain tributary streams in southeastern Michigan. The resulting correlations of these organisms to one another are expected to show the value of Salmonella and other enteric pathogens as water quality indicator organisms. Correlative chemical parameters are also under investigation in order to determine toxicity levels. Control and test areas are being monitored two to three times a week on a yearly basis. Field and laboratory Salmonella survival studies are also being performed in order to determine die-off and comparative survival rates.

The techniques used for Salmonella isolation include: enriching with DSE and tetrathionate broth, streaking on XLD agar, testing biochemically and typing serologically. In the survival studies, tagged Streptococcus liquificans and E. coli are being used for comparison with Salmonella. Field pH and DO are determined using a pH meter, Model Porto-matic IL, and DO meter, Model 51-YSI, both of which are calibrated in the laboratory prior to use. Chemical determinations are being made by atomic absorption.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0634, AN ECOLOGICAL EVALUATION OF STREAM EUTROPHICATION
R.C. BALL, Michigan State University, Institute of Water Research, *East Lansing, Michigan* 48823 (C-2205)

The objectives of the research are (1) to develop indicator indices from analyses of structure and function of selected stream communities for predicting the short term and long term significance of gradual degradation of water quality by human accelerated eutrophication; (2) to obtain sufficient baseline data on water quality and associated community responses in streams on watersheds having different degrees of agricultural and urban drainage to allow for development of systems analysis of aquatic ecosystems; (3) to evaluate the effects of urbanization on stream discharge and concurrently, the relationship of stream stability to the structure of aquatic communities; and (4) to accomplish the preliminary work for developing adequate techniques for quantifying the esthetic and recreational value of a stream and public attitudes toward competing demands on the resource.

Three watersheds on the Lower Peninsula of Michigan have been selected for exhibiting a graded series in degree of eutrophication and urbanization. Four intensive study sites, consisting of from 100 to several hundred meters of contiguous stream, have been located in these watersheds at points where severe, moderate, slight and minimal eutrophication is occurring. The ecosystems of the intensive study sites will be investigated through analyses of (1) community structure, (2) community metabolism, (3) indicators of impending degradation, and (4) water quality. Data concerning these ecosystems will be interpreted in a background of information gathered from the watersheds concerning (1) nitrogen and phosphorus enrichment, (2) pesticide contamination, (3) heavy metal concentrations, (4) stream stability and urbanization, and (5) socioeconomic aspects of stream degradation.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0635, POLLUTION OF A MARINA AREA BY WATERCRAFT USE AS INDICATED BY COLIFORM AND CHEMICAL CONCENTRATIONS
W.N. MACK, Michigan State University, School of Natural Sciences, *East Lansing, Michigan* 48823

The normal coliform and chemical concentration of the water in northern Lake Michigan marina will be determined before the boating season. Tests will be done by Standard Methods. As the season progresses, samples of water will be tested for the dissemination of coliform organisms. The radial spread of the pollution will be followed by using pads suspended in the water to accumulate sample and testing bottom samples. The project will continue beyond the pleasure boating season to determine how soon the chemical and bacterial concentrations will return to their preseason base.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0636, STUDIES ON ALGAE FROM EUTROPHIC AND OLIGOTROPHIC WATER AND THEIR USE IN BIO-ASSAY OF WATER QUALITY
B. MOSS, Michigan State University, Graduate School, *East Lansing, Michigan* 48823

Concern about the nutritional quality of stream and lake water is rapidly growing. On one hand, increasing influx of sewage effluent is promoting growth of undesirable algal blooms in many lakes, and on the other, in underdeveloped countries little basic data exists for the optimal fertilization of fish ponds for producing much needed protein food. Additionally, in siting new drinking water reservoirs, data on the potentialities of local drainage water for the growth of possible 'nuisance' algae is required. In all cases a short term biological assay method for water quality (especially in terms of nitrate and phosphate and their interaction) is required, since chemical analysis alone is often inconclusive.

The mineral nutrient needs, especially of nitrate and phosphate, of algal species carefully chosen for their representativeness of oligotrophic and eutrophic environments will be investigated in cultures. The use of a series of these organisms in the bio-assay of eutrophication will then be evaluated in comparison with field observations, chemical analyses and assays using indigenous algal populations. It is hoped that a standard assay system, of widespread use, and of greater ecological relevance than previous systems using 'laboratory' species, will be evolved. Emphasis will be placed on ease of use and economy of apparatus and materials.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0637, PHYTOPLANKTONIC NITROGEN AS AN INDEX OF CULTURAL EUTROPHICATION
R.G. WETZEL, Michigan State University, Graduate School, *East Lansing, Michigan* 48823

This research is designed to quantify several new aspects of the nitrogen cycle in the aquatic ecosystem. The research will permit evaluation of a model describing nitrate uptake from artificial media and natural environment by phytoplankton. The model relies on a new method for determining phytoplanktonic nitrogen in natural seston distinct from that contributed by the zooplankton, detritus and bacteria. This method is based on physiological relationships between organic nitrogen content and the ratio of plant pigments in the three major algal phyla common to algal blooms.

The predictive power of the model will be investigated and improved under laboratory conditions and in situ with natural phytoplankton under N-enriched and natural conditions. Possible applications of these techniques to both N-deficient and N-enriched situations in lakes will be evaluated with particular emphasis on capabilities for predicting stress effects resulting from cultural eutrophication.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0638, NITRIFICATION IN SURFACE WATERS
C.R. BAILLOD, Michigan Technological Univ., School of Engineering, *Houghton, Michigan* 49931

Increasing attention is being paid to the effect of nitrification on the water quality of surface waters. The objectives of the study, therefore, are: 1. The investigation of the extent of, and potential for, the occurrence of nitrification in surface waters tributary to Lake Superior in Michigan's upper peninsula. 2. The elucidation of significant factors affecting nitrification in surface waters.

In order to determine the extent of nitrification in these waters, it is proposed to institute a sampling program in which bimonthly samples would be taken in streams at points below sources of reduced nitrogen. These samples would be analyzed for all forms of nitrogen. The potential of the various surface waters for nitrification would be determined by batch incubation techniques after the addition of known concentrations of ammonia and nitrifying organisms. A dilution technique would be employed to estimate the concentration of nitrifying organisms. These batch incubation techniques will also be employed to determine the effect of other factors upon nitrification.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0639, THE INVESTIGATION AND ANALYSIS OF BIOCHEMICAL PROCESSES OF AQUATIC ORGANISMS UNDER STRESS
G.M. CHRISTENSEN, U.S. Dept. of the Interior, Federal Water Quality Admin., *Duluth, Minnesota* 55804

The objective of this work is to carry out investigations on a molecular level on organisms, organs, tissues, cells and chemicals of aquatic life which have been exposed to toxicological or noxious situations and stress; to establish base-line data, or normal values, for specific biochemicals or biochemical systems in organisms and also, later, to establish parallel experimental values for those systems when under toxicological or noxious situations and stress. It is proposed that work be done to investigate and clarify the interaction between stress source and stressed system, diagnosis and prognosis. It is proposed that research be carried out in order to determine whether it is possible to carry out a qualitative and quantitative analysis on specific biochemicals in an organism and deduce the general state of health or well-being of that organism or diagnose its ill health and have a basis for making a prognosis regarding its future state or health condition.

Initially, work is being carried out with the general 'fight-or-flight' (stress) hormones, adrenaline and noradrenaline. We are in the process of establishing normal values for these two biochemicals in fish, and plan then to determine non-normal values for the organism when under toxicological or other types of stress. Equipment which is particularly useful for this study includes a recording spectrophotometer, thin-layer and paper chromatographic apparatus, a recording spectrophotofluorometer and a sensitive infra-red spectrophotometer.

Other biochemicals that may be investigated in the future include, tentatively, blood glucose, serum non-protein nitrogen, certain inorganic salts, specific serum enzymes, plasma fatty acids and other specific hormones that are known to be inolved in stress-type biological reactions.

2.0640, BEHAVIOR OF PLATINUM ELECTRODES AS REDOX POTENTIAL INDICATORS IN METALLURGICAL SYSTEMS
I. IWASAKI, Univ. of Minnesota, School of Mineral Engin., *Minneapolis, Minnesota* 55455

Although redox potential measurements are usually made with platinum electrodes, the reliability of the measurements is often overestimated. Certain substances in solution may poison the electrodes so that they give erroneous readings. The nature of these substances, the manner of their absorption on the electrodes, and the means of alleviating their adverse effects are not well understood. This research investigation will start with a few substances known to act as poisons and will be extended to other substances of more interest to the metallurgical industry. The influence of these substances on redox potential measurements will be studied by the triangular wave potential sweep method, the galvanostatic charging method, the differential capacitance method, and by infrared spectroscopy. The knowledge gained will be of practical importance in controlling metallurgical processes in monitoring water pollution problems.

SUPPORTED BY U.S. National Science Foundation

2.0641, EFFECT OF SEWAGE EFFLUENT ON ALGAE IN SHAGAWA LAKE, MINNESOTA
R.O. MEGARD, Univ. of Minnesota, School of Earth Sciences, *Minneapolis, Minnesota* 55455

The first objective of this project is to determine the population densities and daily rates of photosynthesis of the natural phytoplankton populations in Shagawa Lake. This will provide 1) a baseline for evaluating the effectiveness of a tertiary treatment plant that may be constructed and 2) a basis for comparing the productivity of this lake with that of others in the region that have been studied.

The second objective is to perform nutritional bioassays and short- term enrichment experiments in an attempt to determine which nutrients are critical for algal growth at various times of the year. This will be done to help determine what type of nutrient removal is likely to be most effective and to provide a rational basis for designing and estimating the cost of full-scale treatment facilities.

Much of the work will be done in the F.W.P.C.A. laboratory at Ely, Minnesota between September 1, 1969 and August 31, 1970.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0642, ZOOPLANKTON BIOMASS AND INCIPIENT EUTROPHICATION IN LAKE SUPERIOR
T.A. OLSON, Univ. of Minnesota, School of Public Health, *Minneapolis, Minnesota* 55455

This research project will be concerned with detailed zooplankton biomass assessments in selected regions of Western Lake Superior. Areas near Duluth-Superior, near Larsmont and at Grand Marais will be studied. Clarke-Bumpus Nets, Miller High Speed Samplers and the Continuous Plankton Recorder will be employed for zooplankton collections in these regions.

The objective of this investigation is to evaluate various types of zooplankton biomass assessment as a means for measuring subtle beginnings of eutrophication as it may develop in Western Lake Superior. In the studies envisioned, biomass analyses and productivity measurements will be carried on throughout the open water season. Total wet volume, organic matter of the biomass, zooplankton identification and enumeration and other pertinent determinations will be made on the samples. The major emphasis will be on ecological factors, especially those which relate directly to the response of zooplankton organisms to a slight but ever increasing enrichment of the environment.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0643, BENTHONIC INVERTEBRATES AS AN INDEX OF WATER QUALITY
T.A. OLSON, Univ. of Minnesota, School of Public Health, *Minneapolis, Minnesota* 55455

The proposed water pollution study will be made on immature aquatic invertebrates. Primary efforts will continue to be concentrated on the oxygen requirements of each species during its aquatic life cycle. It is believed that through such a study a more exact evaluation can be established on the status of these in-

vertebrates as indicators of water quality or as potential bioassay indicators. A subsequent cataloging of each species should be of value to agencies and persons concerned with water pollution.

Since environmental conditions can be more closely controlled in the laboratory, the work will be centered on this aspect. A limited number of field studies will be included. A flow-through respirometer in which the oxygen is measured by an electrochemical transducer and the conventional Manometric technique will be employed to measure oxygen consumption rates.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0644, LAKE SUPERIOR PERIPHYTON IN RELATION TO WATER QUALITY

T.A. OLSON, Univ. of Minnesota, School of Public Health, *Minneapolis, Minnesota* 55455

This proposal is concerned specifically with the completion of objectives set forth in an approved project of five years begun in 1965. The study dealt with that assemblage of aquatic organisms known as periphyton which grow attached to the submerged surfaces of rocks in Lake Superior.

Of the seven primary objectives stated in the original proposal, only two remain to be investigated. The specific objectives for this proposed final year of the project would be directed toward the determination of (1) the possible changes which occur in the periphyton when polluting substances are introduced into the lake and (2) the possible interrelationships existing between the periphyton and the plankton.

That portion of the study relating to the addition of polluting materials will be undertaken by examining the periphyton by various methods at comparable polluted and unpolluted areas. In addition, certain natural and artificial fertilizers will be introduced in two areas, with a third comparable area serving as a control.

For the purpose of evaluating the interrelationship of periphyton and plankton, simultaneous qualitative and quantitative determinations on the composition of each community will be made with an attempt being made to effectively correlate these.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0645, RELATION OF PHOSPHORUS IN LAKE BOTTOM DEPOSITS AND POLLUTIONAL HISTORY OF MINNESOTA LAKES

J. SHAPIRO, Univ. of Minnesota, School of Earth Sciences, *Minneapolis, Minnesota* 55455

A study is to be made of the phosphorus content of sediment profiles from a wide variety of lakes in Minnesota. The shapes of these profiles will be interpreted in the light of other events as determined through micro-fossil analysis. This study coupled with direct studies of the availability to recycling of phosphorus from different depths in the cores will aid in determining the extent to which sedimentary phosphorus is of meaning to the productivity of lakes.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0646, MATHEMATICAL SIMULATION OF A LARGE WATERSHED USING THE SYSTEMS APPROACH TO QUANTITY AND QUALITY ANALYSIS

C.C. SONG, Univ. of Minnesota, School of Engineering, *Minneapolis, Minnesota* 55414

It is proposed that a comprehensive mathematical model be constructed, simulating the engineering aspect of a typical large water resources system. Starting from suitable mathematical models for each component of the system, such a surface flow, ground water flow, mass transport, movement and change of pollutant, and snow melt, a comprehensive response function of a system will be constructed. The validity of the model will be tested by applying the model to the Minnesota River Watershed using the available field data on physical parameter of the watershed, pollution, and use, precipitation, runoff and the quality of water. Sensitivity analysis of the model will also be carried out.

Depending on the progress made on the initial stage of the investigation, one or more of the following items may also be performed: 1. Stochastic analysis of the input and output of the system and the response of the system to stochastic input. 2. Prediction of the quantity and quality of water in Minnesota river watersheds and comparison with the additional field data. 3. Systems analysis for the purpose of optimum design and management of the watershed.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0647, DIATOMS IN LAKES AND LAKE SEDIMENTS AS AN INDEX TO ENVIRONMENT

H.E. WRIGHT, Univ. of Minnesota, School of Earth Sciences, *Minneapolis, Minnesota* 55455 (AT(11-1)2046)

The project includes four aspects, investigated concurrently: (1) Completion of the survey of living planktonic and sessile diatoms in a representative series of lakes across the state of Minnesota, combined with analyses of surface mud samples, (2) continuation of the collation of chemical and other ecological data from the world literature on diatoms, (3) analysis of short cores of paired polluted and unpolluted lakes, to determine the changes in diatom assemblages resulting from pollution, and (4) analysis of long cores so that the recent changes in diatom assemblages can be compared with those that have occurred throughout postglacial time in response to changes in climate or other natural factors in the environment.

Results to date on short-core analysis, especially in conjunction with other biostratigraphic and chemo-stratigraphic studies, are very promising, and stratigraphic diatom analysis may prove to be a very valuable technique for watching the progress of pollution as well as of other environmental changes.

Result to Date: Short-core diatom analyses for Lake Sallie in northwestern Minnesota show striking changes in diatom assemblage starting at the time of agricultural land clearance in the area, as determined by pollen analysis of the same core. Preliminary results for other lakes point to similar relations.

SUPPORTED BY U.S. Atomic Energy Commission

2.0648, MAYFLY DISTRIBUTION AS A WATER QUALITY INDEX

C.R. FREMLING, Winona State College, Graduate School, *Winona, Minnesota* 55987

Hordes of mayflies rise from the Mississippi River every summer and create nuisance problems for river residents and river traffic. The relative abundance of the various species in a given area, however, is probably a reliable indicator of general water quality in that area.

Adult mayflies will be collected systematically along the Upper Mississippi River. An efficient, reliable, large-scale collection system was initiated in 1957 and it has been in continous operation since that date. Past and future collections will be analyzed to determine (1) geographical distribution of the various species, (2) times of adult emergence, (3) areas of scarcity and abundance, (4) population trends, and other basic biological data. Most important, this analysis will determine the present state of the river as habitat for pollution-sensitive organisms. These data will provide a basis for comparison, should the quality of the aquatic habitat change in the future.

I have developed methods for rearing large numbers of burrowing mayflies in the laboratory. Laboratory populations will be maintained to determine the effects of limiting factors such as concentrations of dissolved substances, food supply, temperature, intraspecific strife and interspecific competition. The degree to which burrowing mayflies contribute to total turbidity will be determined. Laboratory populations will also be studied to learn more concerning the environmental factors which coordinate mass rhythmic emergences of mayflies.

Laboratory experiments in conjunction with field investigations will enable me to evaluate the importance of the various roles played by mayflies in the aquatic ecosystem. This evaluation becomes increasingly important as river cities contemplate mayfly control programs.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0649, WATER RESOURCES OF COPIAH COUNTY

T.N. SHOWS, State Geol. Survey & Wa. Reso., *Jackson, Mississippi* 39201

The water resources investigation of Copiah County was started in the summer of 1967. Emphasis was placed on obtaining information on the aquifers within the County as all domestic and industrial supplies are from ground-reservoirs. Surface water data is needed to provide information to industries which might be users of surface reservoirs to supplement ground-water supplies. The Pearl River which forms the eastern boundary is large enough to provide water to industry, except that upstream pollution has limited the usefulness of this water.

The Survey will be able to provide answers to questions of quantity, quality and availability of ground and surface water in Copiah County. Some of the methods used in collecting ground-water information in Copiah County are: running aquifer performance tests, monitoring water level changes, collecting water samples for chemical analyses, drilling test holes to determine the presence and extent of aquifers, inventorying existing wells with emphasis on the large industrial and municipal wells, and running electrical logs.

Records of stream flow, including maximum and minimum flow, and chemical analyses of surface water are being compiled from available published and unpublished sources. Low flow data and partial chemical analyses are being collected on various streams in the County.

SUPPORTED BY Mississippi State Government

2.0650, WATER RESOURCES OF RANKIN COUNTY

T.N. SNOWS, State Geol. Survey & Wa. Reso., *Jackson, Mississippi* 39201

The water resources study of Rankin County was begun in the Spring of 1969. Major study is concentrated on defining the principal aquifers underlying the County as all domestic and industrial supplies are from ground-water sources. Surface water information will determine if a dependable supplementary water supply is available for future use. The Pearl River Reservoir and the Pearl River north of Jackson have the potential of furnishing large amounts of surface water to major users. Presently the water supply for the City of Jackson (on the west side of the River) is from the Pearl River north of Jackson The reach of the River below Jackson is polluted by municipal and industrial waste.

The primary responsibility of the Survey is to appraise the water resources of the County. Questions will be answered as to quantity, quality and availability of ground and surface water in Rankin County. Answers to these questions will assist in the orderly development of the water resources. Some of the techniques used in collecting ground- water information in Rankin County are: running aquifer performances tests, drilling test holes to determine the presence and extent of aquifers, inventorying existing wells with emphasis on large industrial and municipal wells, collecting pumpage and quality of water information, and running electrical logs.

Surface water records including both published and unpublished records are being analyzed for useful information from various governmental organizations.

SUPPORTED BY Mississippi State Government

2.0651, A STUDY OF THE DEPURATION PROCESS IN OYSTERS TAKEN FROM POLLUTED WATERS AND RE-BEDDED IN UNPOLLUTED WATERS

D.W. COOK, State Marine Conserv. Comm., *Ocean Springs, Mississippi* 39564

This phase is a continuation of Phase III of Sub-Project 2-28-R-2.

Objectives: To study the depuration of pollution indicator bacteria from oysters relaid into clean waters and to study the changes that occur in the composition of oyster meats during depuration.

Procedures: Oysters will be moved from polluted waters to clean waters, sampled periodically and analyzed bacteriologically and chemically. Bacteriological analysis for the coliform MPN, fecal coliform MPN and total plate count will be conducted in accordance with 'Recommended Procedures for Bacteriological Examination of Sea Water and Shellfish', American Public Health Service Association, 1962. Chemical analysis for the total dry weight, glycogen, protein and ash content will be made using standard procedures.

Part 2 of 3

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.0652, A STUDY OF COLIFORM BACTERIA AND ESCHERICHIA COLI ON POLLUTED AND UNPOLLUTED OYSTER BOTTOMS OF MISSISSIPPI

G GUNTER, State Marine Conserv. Comm., *Ocean Springs, Mississippi* 39564

Objectives: 1) To establish a regular sampling program on transects across Mississippi Sound and extending from fresh water to the Gulf of Mexico and on selected polluted and unpolluted oyster reefs. 2) To perfect technique for collecting comparable samples. 3) To complete bacterial analyses of collected samples. 4) To compare the bacterial flora from polluted and unpolluted areas of Mississippi Sound and adjacent waters, especially as it relates to sewage polluted oyster beds.

Procedures: 1) Field - (a) Surface, mid-water and bottom samples will be collected at established stations where there is sufficient depth of water. Additional samples will be collected as necessary. (b) Techniques to insure the collection of samples under sterile conditions will be established. (c) Temperature and salinity will be determined at all stations. (d) Collected samples will be refrigerated and returned to the laboratory for analysis. 2) Laboratory - (a) The most probable number of coliform organisms and of Escherichia coli of presumptive human fecal origin will be determined by competent bacteriologists. (b) Additional studies will be carried out where feasible.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.0653, PHYSICAL AND CHEMICAL PROPERTIES OF SEDIMENTS

L.L. MCDOWELL, U.S. Dept. of Agriculture, Sedimentation Laboratory, *Oxford, Mississippi* 38655 (SWCW1-BE-4)

OBJECTIVE: Extend knowledge of the deleterious and beneficial physical and chemical attributes of sediments in runoff waters, in channel deposits, and in impoundments.

APPROACH: Obtain sediment samples for analysis and evaluation at selected sites in the Lower Mississippi River and some principal tributaries, in selected channels draining agricultural lands, and in selected reservoirs and impoundments. Factors involved include dispersion and flocculation tendencies, exposure to air and sunlight, water depths in reservoirs, age and depth of submerged sediments, and other environments.

PROGRESS: Analyses for pesticides content of streambed samples of the Lower Mississippi River and many of its tributaries taken during 1966 and 1967 generally confirm the findings from the 1967 sampling and reported in the American Society of Agronomy Special Publication No. 8, November 1966. Many of the samples obtained near a manufacturing plant for endrin and heptachlor, or near the plants of formulators, had measurable amounts of dieldrin, aldrin, endrin, isodrin, X, Y, chlordane, lindane, and DDT analogs and metabolites. On the other hand, with only one exception, DDT analogs and metabolites were the only pesticide residues found that originated from nonindustrial sources, i.e., municipal and agricultural; and many of these residues were found at concentrations less that 0.05 ppm. Of 125 samples collected in 1966 from tributary streams in Mississippi, Arkansas, and Louisiana, half had no measurable pesticides, a third contained measurable DDT or its associates only, and a sixth had additional pesticides. Improvements in analysis techniques have resulted in the detection of chemicals not previously found, and in the detection of all at lower levels of concentration. But, the principal conclusion of the 1964 sampling program still holds. That is, that the large quantities of pesticides previously applied to crops in the Mississippi Delta have not created widespread, de-

tectable contamination of streambed materials. This is not to say that no contamination was found.

SUPPORTED BY U.S. Dept. of Agriculture

2.0654, A STUDY OF THE ECOLOGY OF THE MISSISSIPPI TEST FACILITY

L.R. BROWN, Mississippi St. University, Inst. for Space Env. Sci. Eng., *State College, Mississippi* 39762

The objective of this project is to determine the 'baseline' conditions of selected waters and the lands of both the fee zone and the buffer zone at the Mississippi Test Facility. More specifically, qualitative and semi-quantitative estimates of the aquatic and terrestrial flora and fauna will be made along with preliminary chemical and physical characterization of the waters.

It is expected that the information obtained in this investigation coupled with information already available on the area will allow for a reasonably complete characterization of the ecological/environmental conditions existing at the Facility.

SUPPORTED BY U.S. Natl. Aero. & Space Adm

2.0655, DEVELOP IN-HOUSE CAPABILITY IN WATER QUALITY TECHNIQUES FOR ANALYSES OF HEAVY METALS, BACTERIA, AND PESTICIDE RESIDUES

C.F. DERRINGTON, U.S. Army, Corps of Engineers, *Vicksburg, Mississippi*

Technical Objective: The purpose of this program is to develop an in-house capability for analyzing water samples and related materials for pollutants such as heavy metals, bacteria, and pesticides. Optimum parameters will be developed or determined for the analysis of these pollutants. The program will provide the U. S. Army Corps of Engineers with the badly needed capability of analyzing water samples to determine what pollutants are present and their respective concentrations.

SUPPORTED BY U.S. Dept. of Defense - Army

2.0656, POTENTIOMETRIC TECHNIQUES FOR MONITORING IONS INVOLVED IN WATER POLLUTION

S.E. MANAHAN, Univ. of Missouri, School of Arts, *Columbia, Missouri* 65202

New and improved potentiometric techniques are being developed to monitor ions, particularly monovalent anions, of interest in water quality control. Cells without liquid junction using the fluoride electrode as a reference are being used with a standard addition technique to determine concentrations of nitrate and other anions. Methods are being explored to utilize the nitrate ion-selective electrode to follow nitrate assimilations in algal cultures. The nitrate ion-selective electrode enables the continuous monitoring of nitrate ion concentration in algal cultures. The effects of light intensity, carbon dioxide concentration and alternative nitrogen sources are being explored.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0657, AUTOMATED POTENTIOMETRIC TECHNIQUES FOR THE ON-SITE MONITORING OF IONS IMPORTANT IN WATER QUALITY CONTROL

S.E. MANAHAN, Univ. of Missouri, Graduate School, *Columbia, Missouri* 65202

The overall objective of the proposed research is the development of new and improved techniques applicable to the automated monitoring of low concentrations of ions in water. Methods are to be developed which are simple, fast, reliable, sensitive and low in cost per sample. The analysis techniques will require a minimum of operator time.

Methods and hardware to be developed include (1) a multisensor analysis system, (2) a standard addition technique, (3) stable, low- leakage, low-drift reference electrodes, and (4) a flow titration technique. Emphasis initially will be on nitrate and cyanide ions. Later the work will be extended to other ions such as sulfate, fluoride, chloride, bromide, iodide, lead and copper.

Ion-selective electrodes will form the basis of the analysis system.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0658, A STUDY OF THE WATER QUALITY AND PLANKTON DYNAMICS OF LAKE JACOMO, THE PRIMARY RECREATIONAL WATER FOR GREATER KANSAS CITY

D.H. STERN, Univ. of Missouri, Graduate School, *Columbia, Missouri* 65202

The proposed one-year study has as its goals the quantitation, analysis, and interpretation of the interrelationships between physical, chemical, and biological parameters in Lake Jacomo, a 970-acre recreational reservoir serving yearly over 1,000,000 residents of the Kansas City metropolitan area. Physicochemical factors to be examined include water temperature, dissolved oxygen, light transmission, pH, specific conductance, turbidity, ammonia-, nitrite-, and nitrate- nitrogen, phosphate, silica, total and phenolphthalein alkalinities, and total and calcium hardness.

Biological factors examined will include the identification and quantitation of the plankton (determination of standing crop) and productivity studies (light & dark bottle). While gaining the requisite information, we shall consider the following points: (1) the effects of eutrophication of lake water by runoff from surrounding farmlands and feed lots: (2) the quality of the water with respect to primary and secondary recreation and aesthetics; (3) the acquisition of baseline information for comparison of changes in water quality at other seasons and during succeeding years; (4) the presence of sources of pollution in the lake waters; and (5) recommendations for the management of Lake Jacomo and other reservoir lakes soon to be constructed.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch

2.0659, WATER QUALITY OF THE NORTH, SALT, AND CUIVRE RIVER BASINS

M.D. MCDANIEL, State Dept. of Conserv., *Jefferson City, Missouri* 65102

Objectives: To study existing biological conditions in the streams and to acquire the necessary background data for evaluating the effects of pollution at present and in the future.

Procedures: A series of approximately 50 stations will be strategically located within the three stream basins. Biological samples will be collected at these stations once during each season of the year. At the time of these collections, physicochemical and flow measurements will be made by the Missouri Water Pollution Board and U.S. Geological Survey personnel.

Biological collections will include qualitative, semi-quantitative benthos samples which will be collected from both pool and riffle habitats at each station where practicable. A portion of stream will be surveyed at each station for larger aquatic invertebrates such as mussels, crayfish, and snails. Qualitative algae samples will also be taken at each sampling. Fishes will be surveyed once at all stations to determine species present.

A standard form will be used to record kind and relative numbers of benthic organisms present at each station. Identification of organisms will be as follows: (a) Flatworms, annelids, and roundworms will be identified to class. (b) Flies (Diptera) will be identified to family or genus when practicable. (c) Stoneflies, mayflies, caddisflies, crayfish, and mussels will be identified to species when practicable. (d) Snails, crustaceans, and macro-invertebrate groups other than those named will be identified to genus when practicable.

Data from the stations will be tabulated seasonally and compared. As benthos samples will be more qualitative than quantitative, data analyses will emphasize diversity rather than density. Correlation of benthic data to physico-chemical water quality factors will be emphasized in the final report. Information from this report will be included in a comprehensive final report for the entire cooperative project.

2. WATER QUALITY

SUPPORTED BY Missouri State Government

2.0660, A PROPOSAL TO DEVELOP A PLAN FOR THE CONSTRUCTION AND TESTING OF WATER POLLUTION FORECASTING MODELS
G.E. STAATS, Univ. of Missouri, School of Engineering, *Rolla, Missouri* 65401

One important aspect of the overall water pollution program in the United States is the prediction of water needs, quality levels and pollution levels. These predictions can be made with statistical forecasting models. In order to develop these models, a number of different phases must be undertaken. These phases of the research plan are: Phase 1 - An Exhaustive Evaluation of the Pertinent Literature. Phase 2 - Analyze the State Water Supply System and Select a Small Sub- system. Phase 3 - Determine Water and Pollution Inputs, and Water Outputs of the Sub-system Selected in Phase 2. Phase 4 - Develop Potential Relationships Between Independent Variables and the Dependent Variables, Water and Pollution Inputs, and Water Outputs. Phase 5 - Design the Experiment to Test and Evaluate the Relationships Developed in Phase 4. Phase 6 - Develop the Plan for Carrying Out the Experiment Designed in Phase 5.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0661, SOURCES OF SEDIMENT IN A MOUNTAIN RIVER BASIN
M.G. KLAGES, Montana State University, School of Agriculture, *Bozeman, Montana* 59715

This project is designed to test the feasibility of using minerals as tracers to determine the source and type of materials carried in suspension by a river. This would enable one to make a pollution analysis to determine the source and type of pollutants at any point on a stream. This would greatly facilitate the data gathering for pollution analysis.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0662, TESTACEA (PROTOZOA - SARCODINA) AS INDICATORS OF WATER QUALITY IN WESTERN MONTANA
J.F. TIBBS, Univ. of Montana, School of Arts, *Missoula, Montana* 59801

This research would include field and laboratory investigations directed toward: 1. Determination of species composition of the assemblages of testate amoebae characteristic of aquatic habitats in western Montana. 2. Establishing whether association of testaceans may be used as indicators of water quality with reference to chemical and biological criteria. 3. Study of the biology of selected species which are amenable to laboratory culture. 4. Study of the ecology and the utility as indicator organisms of the Cyphoderia ampulla complex.

Associated chemical and physical data would be collected in a variety of aquatic habitats. Each of these habitats would be repeatedly sampled in 1969 and 1970, and pertinent chemical and physical data would be collected at the times of sampling.

Determinations of Species and other laboratory work will be correlated with field data with a view toward practical application of the findings.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0663, MERCURY CONCENTRATIONS IN THE AQUATIC LIFE FORMS AND THE WATERS OF THE UPPER CLARK FORK RIVER
W.P. VANMETER, Univ. of Montana, School of Arts, *Missoula, Montana* 59801

This research effort will be directed to establishing analytical techniques to establish mercury concentrations in fish, aquatic insect and crustacean or mollusk tissues. There has been considerable recent attention given to the fact that mercury has been found in the tissues of wild game fish in Western Montana.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0664, HEAVY METAL RESIDUES IN CHANNEL CATFISH FROM SELECTED WATERSHEDS IN NEBRASKA
N. STUCKY, State Game & Parks Commission, *Lincoln, Nebraska* 68509

Objective: To determine whether channel catfish in selected watersheds throughout Nebraska are carrying residues of any, or all, of the following heavy metals: Mercury, chromium, lead, zinc, cadmium, and copper.

Procedure: 1. Channel catfish were collected from seven drainage systems throughout Nebraska during segment 16. Additional collections will be made from four lakes. 2. All samples will be analyzed for mercury whereas selected samples will be analyzed for the other heavy metals. 3. Analysis will be performed with an atomic absorption spectrophotometer for all the metals except lead. The method of choice for lead is dithiozone colorimetric analysis. 4. Those aspects of the study which warrant publication will be published.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0665, UTILIZATION OF THE STORAGE POTENTIAL OF RIVER VALLEY AQUIFERS
R.R. MARLETTE, Univ. of Nebraska, School of Engineering, *Lincoln, Nebraska* 68508

The Water Resources Research Category of this project would be IV. Water Quantity Management and Control, Groundwater Management. The first work would augment the meager water quality data available in the lower Platte River basin with a systematic sampling and analysis of the physical, chemical and biological features of these rivers' water. The aim would be to determine the important characteristics and develop simplified testing procedures for using river water to recharge valley aquifers.

The seasonal quality of the Elkhorn, Loup and Platte rivers will be analyzed to determine the treatment, if any, that may be required in order to use these waters to recharge through infiltration basins located near production wells. The sampling will take place within a fifty mile radius of Lincoln, Nebraska. Some of the analysis will be done in the field, but most of this work will be performed in the Sanitary Laboratory of the Civil Engineering Department.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0666, INTERACTION OF RADIO-LABELLED BIOCIDES AND HEAVY METALS WITH MICROBIAL ECOSYSTEMS
R. KOKKE, Technische Hogesch. Te Delft, *Delft, Netherlands*

A study is made on: 1. With radiotracer methods of accumulation, retention, excretion and conversion of biocides and heavy metals by microbes in pure culture, in soil and in an aqueous ecosystem (activated sludge). 2. The effects of the chemical on microbial strains and ecosystems. Particular attention is paid to synergistic and antagonistic effects. 3. Improvement of analytical and quantification techniques which are required for the study of the interactions of the chemicals and the microbes.

SUPPORTED BY Intl. Atomic Energy Agency - Austria

2.0667, LIMNOLOGICAL INVESTIGATIONS OF LAKE MEAD
D. LOCKARD, State Dept. of Fish & Game, *Las Vegas, Nevada*

Objectives: To determine significant physical or chemical changes within Lake Mead which may be attributed to upstream impoundments.

To determine the extent of pollution which is occurring at the Las Vegas Wash portion of Lake Mead.

Procedures: Standard methods will be used in collecting temperature profiles, dissolved oxygen and various chemical and physical data from established sampling areas of the lake. This data will be gathered on a seasonal basis. Correlation of this information with previous samplings and upstream conditions will be accomplished.

In conjunction with local and State pollution control agencies, a systematic monitoring of the Las Vegas Wash area will be accomplished.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0668, ENVIRONMENTAL REQUIREMENTS OF SELECTED ESTUARINE CILIATED PROTOZOA
A.C. BORROR, Univ. of New Hampshire, Graduate School, *Durham, New Hampshire* 03824

This study is designed to determine the possible role of ciliated micro organisms (phylum protozoa, class ciliophora) as water pollution indicators. It will involve investigation of factors affecting species composition and micro distribution of populations of intertidal ciliates of the tidal marshes of the Great Bay-Little Bay Estuary, New Hampshire, where they reach particularly high population densities. The relationship of ciliates to the rest of the decomposor food chain, and their role in estuarine productivity will be investigated. Measurements of relative and absolute abundance of members of microbenthos, correlated with variations in physical and chemical factors, will be employed in assessing diurnal and seasonal changes in ciliate community structure.

The research will be carried out using facilities at the Univ. of N.H. and at the Jackson Estuarine Laboratory, Univ. of N.H., on Adams Point, Great Bay, N.H. Research will include examination of living ciliates augmented with material prepared according to standard fixation and staining procedures as well as associated environmental data. The project is due to commence on October 1, 1969 and is to conclude on September 30, 1972.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0669, POPULATION STUDIES OF MARINE AMPHIPOD CRUSTACEANS
R.A. CROKER, Univ. of New Hampshire, School of Liberal Arts, *Durham, New Hampshire* 03824

The investigations supported by these funds concern a comparative field and laboratory study of population structure and ecological specialization in two groups of marine amphipod crustaceans found in estuarine and shallow sea environments. Organisms of one group (Gammaridae) live on rocky, algal and muddy substrata; while those of the other group (Haustoriidae) are found living within sediments. The objectives of this research are to investigate: (1) population structure, including local and regional patterns of distribution, fluctuations, clines, intergradations, peripheral populations and ecological replacement of species; and (2) the morphological variation of species as related to ecological specialization. The data resulting from these investigations will be valuable in predicting the consequences of modification of estuarine and shallow sea environments, and will contribute to a better understanding of the population biology of crustaceans in estuarine complexes which experience changing levels of pollution.

SUPPORTED BY U.S. National Science Foundation

2.0670, A STUDY OF ALGAL POPULATIONS ASSOCIATED WITH DIFFERENT LEVELS OF WATER QUALITY IN NEW HAMPSHIRE
A.C. MATHIESON, Univ. of New Hampshire, Graduate School, *Durham, New Hampshire* 03824

In the present investigation the species composition, periodicity and abundance of algal populations from three areas (Newfound Lake, Winnisquam Lake and New Hampton Stabilization Pond and Lake Winnepesaukee differing with respect to water quality, will be compared in order to assist in the prediction, prevention, and control of algal blooms in New Hampshire water supplies. These three areas show a marked difference with respect to pollution, i.e., Newfound Lake has no pollution, Winnisquam Lake is moderately polluted and New Hampton Stabilization Pond is an oxidation pond, or sewage lagoon, which is extremely polluted. A comparative study of this nature will assist in the maintenance of a high quality water supply.

Weekly samples will be taken at New Hampton Stabilization Pond, while collections will be made on alternate weeks at Winnisquam and Newfound Lakes. Samples from New Hampton Stabilization Pond will be primarily restricted to phytoplankton and floating mats of algae, while those from Newfound and Winnisquam lakes will include the attached bottom forms and the epiphytic types as well. The types, abundance, and occurrence of algae at all three areas will be enumerated throughout the year. Various techniques will be employed - Sedgwick-Rafter slide technique as outlined by Palmer (1959), a modificaton of the Hess Method for floating vegetation, collection of host plants and epiphytes, bottom sampling by dredging. Statistical differences will be determined between the various populations and areas studied. Routine culturing of several of the algae will be an integral part of this study - for identification of species and determination of nutrient requirements.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0671, DETECTION AND ENUMERATION OF VIRUS IN NATURAL WATERS
T.G. METCALF, Univ. of New Hampshire, Graduate School, *Durham, New Hampshire* 03824

It is proposed to introduce equipment and methods which will make it possible to determine the presence of virus populations in surface waters on a quantitative basis. The proposed study is directed towards development of the capability for routine quantitative monitoring of the microbiological quality of surface water. The proposal recognizes the great need for addition of a quantitative capability to existing qualitative methods for detecting the presence of viral macromolecules in water. The proposed study anticipates the forging of a powerful technical tool which can be directed toward the solution of a variety of existing problems of both fundamental and applied nature involving the virus macromolecule in water.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0672, CONFERENCE ON POLLUTION OF ESTUARIES
L. WOOD, Univ. of New Hampshire, Graduate School, *Durham, New Hampshire* 03824

Funds from this grant support, in part, a symposium entitled 'Pollution of Estuaries: A NEERS Symposium', held in late May 1970 at the New England Center for Continuing Education, Durham, New Hampshire, under the sponsorship of the New England Estuarine Research Society (NEERS). The major objectives of the symposium are an assessment of current estuarine pollution and the related problems; the identification of those by-products and practices of human society that clearly endanger these important waters; the disclosure of areas in need of further study; and the promulgation of recommendations for actions which will be economically feasible and ecologically sound.

SUPPORTED BY U.S. National Science Foundation

2.0673, SPECIAL TEMPERATURE SURVEY OF RIVER AND ESTUARINE AREAS IN RELATION TO THERMAL POLLUTION AND FISHERY PROBLEMS
T. AZAROVITZ, U.S. Dept. of the Interior, Bur. of Sport Fish. & Wildlife, *Highlands, New Jersey* 07732

The objective is to determine seasonal variations in the surface temperature configuration of rivers and estuaries. These near-synoptic data are to provide baseline temperatures for present and future fishery and ecological studies, especially where thermal additions are a critical factor.

Infrared sensors mounted in helicopters will be the principal method of obtaining temperatures. Surveys will consist of a general gathering of temperature data in rivers and estuaries as well as detailed studies of specific areas where ecological conditions may be obtained by lowering a thermistor and other sampling devices from the helicopter. The cooperation of Federal and State researchers working at areas of interest will be sought to provide additional data.

2. WATER QUALITY

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0674, DISTRIBUTION OF AUTOTROPHIC NITRIFYING BACTERIA IN A POLLUTED STREAM
M.S. FINSTEIN, Rutgers the State University, School of Arts, *New Brunswick, New Jersey* 08903

It is proposed to investigate the distribution of autotrophic nitrifying bacteria in parts of the Passaic River.

The densities of ammonia and nitrite oxidizing autotrophs will be determined in the following environments: water, suspended particulate matter, mud-water interfaces, slimes on rocks and other projecting surfaces. It will be determined if nitrifying bacteria are present as single cells or in multi-cell aggregate in the water phase. Field sampling will be scheduled during different seasons to evaluate the effect of temperature. Sampling sites will be at various distances from outfalls. Ancillary chemical data collected will include - organic nitrogen (tentative), protein, ammonia, nitrite, nitrate and pH; water temperatures will be recorded.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0675, A STUDY OF THE FACTORS DETERMINING THE OXYGEN UPTAKE OF BENTHAL STREAM DEPOSITS
J.F. HUNTER, Rutgers the State University, Graduate School *New Brunswick, New Jersey* 08903

The proposed research involves both a field and laboratory investigation into the factors that determine the oxygen uptake of benthal deposits. The field analyses will involve mud pH, O2 uptake (in situ), temperature, depth, extent or area and water temperature, pH, flow, velocity and depth. Samples of water will be obtained and returned to the laboratory for phosphate and nitrogen determinations, sample of mud for percent moisture, phosphates, particle size distribution, volatile solids, warburg BOD, organic carbon, organic nitrogen, COD, extractables, proteins, carbohydrates, DNA and humic acid.

The information obtained in this study would lead to a better understanding of the process of benthal decomposition, the effect of resuspension of such deposits on the stream and the nutrient reservoir represented by such deposits.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0676, DYNAMICS OF BIOCHEMICAL OXYGEN DEMAND
W. WHIPPLE, Rutgers the State University, Water Resources Research Inst., *New Brunswick, New Jersey* 08903

A quantitative evaluation of biochemical oxygen demand in the rivers of Northern New Jersey. Preliminary studies have indicated that the pollution in these rivers is much larger than can be accounted for by BOD of known effluents. Further research will be conducted into various aspects which might affect this relationship including sedimentation and scour, benthal effects, temperature variation of parameters, nitrogenous BOD, the reliability of 5-day BOD's, and the mathematical variation of carbonaceous BOD with time. Results obtained should be of scientific interest, and also important from planning viewpoints.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0677, GROUND AND SURFACE WATERS - POLLUTION
A.J. KAPLOVSKY, Princeton University, Agricultural Experiment Sta., *Princeton, New Jersey* 08540 (NJ00527)

OBJECTIVE: Development of analytical methods for detecting pesticides, herbicides and phenols in water; determine presence and morphological, cultural, physiological and chemical characteristics of populations of bacteria in polluted waters; environmental factors affecting bacterial pollution of well waters and stream self- purification; factors affecting efficiency of septic tank operations

APPROACH: Current analytical methods will be modified, tested and used in analyses of representative samples of potable waters. Model systems will be developed for laboratory studies of bacteria appearing in polluted water. Effectiveness of various diatomaceous materials for removing bacteria from polluted water will be evaluated in relation to flow. The relative rates of oxidation of organic particles of varying sizes will be determined. Septic tank efficiency work will relate effluent characteristics to soil characteristics.

PROGRESS: Runoff from crop raising areas was primary source of nutrients in sufficient concentration to cause eutrophication. Drainage from pastures contributed to nutrient level but significant source of pollution from area was coliforms. 'Straight-line' or linear estuary built in control temperature room which permits concentrating upon biological parameters of estuary. Will demonstrate the predictability of nitrification in estuarine waters. Simple, sensitive and rapid procedure was developed for separation and identification of extremely low concentrations of halogenated phenols in water. Procedure involves conversion of phenols into corresponding antipyryl or p-nitrophenyl azo derivatives. The rate and extent of oxygen uptakes of stream waters representing various land usages were determined. Role of nutrients, nitrification, and sedimentation under study. Data collected to determine whether or not photosynthetic reoxygenation can be predicted from knowledge of light intensity and such stream analyses as temperatures, color, turbidity, nutrient level and chlorophyl. Data under analysis and evaluation. Lab reaeration apparatus consisting of cylinders mixed in manner analogous to streams modified to contain river muds. Using Passaic River water no significant differences between measured and literature oxygen saturation values. Evaluation of effect of river contaminants on reoxygenation rate in progress.

SUPPORTED BY U.S. Dept. of Agriculture

2.0678, UPPER DELAWARE WASTE ASSIMILATIVE CAPACITY MODEL
P.K. MACEWEN, Delaware River Basin Comm., *Trenton, New Jersey*

The proposed work will be done in two phases: In Phase 1, the efforts would be concentrated on the fifty-mile reach of the Delaware River between Trenton and Phillipsburg. Measurements will be made of the following instream quality parameters: 1) dissolved oxygen; 2) temperature; 3) pH; 4) long-term BODs at selected stations; 5) suspended solids; 6) nitrogen series; 7) chlorophy 11 (A); and 8) soluble phosphate. In addition, measurements will be made of the same parameters of each of the major dischargers. Results of this preliminary field survey, together with historic information will be employed to develop a preliminary steady state mathematical model of DO in the Delaware River. It is anticipated that this preliminary work will be adequate to define the major factors which are influencing water quality within this stretch of the river. In addition, Phase 1 will more clearly define the sampling stations which will be needed under the Phase 11 field investigation.

Phase 11 would consist of an intensive sampling program coupled with the application and full verification of a time variable mathematical model. These models would be used to evaluate the assimilative capacity of the river, study increases in aquatic plant growth and, where needed, allocate receiving capacity to waste dischargers.

SUPPORTED BY Delaware River Basin Comm. - Washington

2.0679, SURVEY OF LAKE NO. 1, WINSLOW TRACT
R.W. STEWART, State Div. of Fish & Game, *Trenton, New Jersey* 08625

Objective: To monitor the development of the fish population and selected environmental factors for the purpose of establishing baselines upon which to consider management of Lake No. 1, Winslow Tract.

Procedure: Efforts during this project segment will be directed toward obtaining additional biological data on the present fish population and further development of procedural sampling techniques.

Information on species composition, abundance and reproductive success along with data necessary for the determination of growth rates and food habits will be collected during the

spring and/or summer by one or more of the following methods: a. Swingle seining techniques. b. Gill nets. c. Short-period simultaneous mark and recovery technique utilizing electro-fishing gear to capture fish. d. Any other method that shows promise. Routine water chemistry data will be collected as considered appropriate.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0680, TIME-OF-TRAVEL MEASUREMENTS IN NEW JERSEY STREAMS
E. DONSKY, U.S. Dept. of the Interior, Geological Survey, *Trenton, New Jersey* 08607

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of New Jersey and the Delaware River Basin Commission.

Purpose: To obtain more knowledge of the movement of materials introduced into river systems such as contaminants that are either water soluble or dispersed in a fine suspension.

Methods: Fluorescent dyes or similar materials will be used to accurately estimate the time required for a soluble contaminant to pass through finite lengths of the major stream systems in New Jersey.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0681, RECOVERY, SEPARATION AND IDENTIFICATION OF PHENOLIC COMPOUNDS, NEW JERSEY
S.D. FAUST, U.S. Dept. of the Interior, Geological Survey, *Trenton, New Jersey* 08607

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of New Jersey.

Purpose: To investigate the recovery, separation, and identification of phenolic compounds from streams.

Methods: Samples were collected from streams where significant 'total' phenolic compound concentrations have been observed previously. Solvent extraction and/or steam distillation techniques will be employed to recover the phenolic compounds from the water samples. Gas-liquid and thin-layer chromatography, and ultraviolet, visible, and infrared spectrophotometric techniques will be employed for separation and identification.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0682, TIDAL DISCHARGE RESEARCH, NEW JERSEY
A.C. LENDO, U.S. Dept. of the Interior, Geological Survey, *Trenton, New Jersey* 08607

This research is part of the program of water resources investigations conducted by the U. S. Geological Survey in cooperation with the State of New Jersey, the Corps of Engineers, and the Federal Water Pollution Control Administration.

Purpose: To develop and improve techniques for the collection of tidal stage, discharge, quality of water, and sediment data.

Methods: Synchronous records of tidal stage have been collected by digital recorders at estuary stations, computer programs are used to compile these records. Discharge equations have also been programmed and calibration has been based on observed discharge by diographs and other parameters by field measurement. Suspended-sediment, particle- size, and other water-quality information is collected during discharge calibration measurements to define changes during tidal cycles.

SUPPORTED BY U.S. Dept. of Interior - Geological Survey

2.0683, SOILS, PESTICIDES AND THE QUALITY OF WATER
H.E. DREGNE, New Mexico State University, Agricultural Experiment Sta., *Las Cruces, New Mexico* 88070 (NM00149)

OBJECTIVE: Identify and characterize the physical-chemical properties of the pesticide-soil-water system which are pertinent to pesticide transport through the soil in infiltrating water, and pesticide desorption from eroded soil into surface waters. Develop mathematical model(s) which will provide semiquantitative prediction of pesticide movement in soil-water systems based on input data obtained in objective above. Measure pesticide transport through and over soil in the field or in lysimeters, using well characterized initial and boundary conditions.

APPROACH: Determine adsorption, desorption, and movement of 3 herbicides (2,4-D, 2,4,5-T, and picloram) in soils, using laboratory columns, soil thin-layer plates, bioassay, radiotracers, and large greenhouse lysimeters.

PROGRESS: 2,4-D is capable of persisting for months in a water- logged soil. Approximately 40 percent of the 2,4-D applied to the surface of a slowly permeable (0.3 ml/hour) silty clay loam was recovered in the leachate after continuous leaching over a period of ten months. Bioassay tests of the soil after leaching showed that 2,4-D remained in the soil at phytotoxic levels, using cucumbers as the test plant. Single factor correlation between 2,4-D movement and soil organic matter level, clay content, carbonate content, and pH was poor in six soils from New Mexico that were tested by soil thin-layer chromatography. The importance of any one soil factors tends to be obscured when other factors vary simultaneously or at random. Preliminary tests on soil thin-layer plates indicated that relative solubility of 2,4-D and 2,4,5-T is a good predictor of their movement. It should also be a good indicator of absorption and desorption by soils.

SUPPORTED BY U.S. Dept. of Agriculture

2.0684, BIOASSAYS OF QUALITY IN WATER RESOURCES OF MAJOR IMPORTANCE TO NEW MEXICO
G.S. SMITH, New Mexico State University, School of Agriculture, *Las Cruces, New Mexico* 88001

Samples of water will be collected seasonally from resources of major importance and assayed for quality in terms of usage by animals and humans. Bioassays will involve study of effects upon pregnant female mice and their offspring when samples serve as the sole source of drinking water. Number, size, mortality and other features of offspring in litters will be scored quantitatively as well as growth rates for offspring from birth to weaning. Samples will be assayed also in terms of effects upon rumen microorganisms cultured in vitro, using urea nitrogen utilization and cellulose degradation as primary criteria. Conventional analyses for chemical constituents and coliform counts will be employed, as well as gas chromatography to measure organic components in samples. All data will be programmed and analyzed by computer for interclass correlations and multiple regressions to identify and quantitate effects of individual components and significant interactions.

2.0685, INVESTIGATION OF THE THERMAL PATTERNS IN THE VICINITY OF THE CRYSTAL RIVER
R.C. ZIEGLER, Cornell Aeronautical Lab. Inc., *Buffalo, New York* 14221

The objective of this program is to collect surface temperature data for the Gulf of Mexico in the vicinity of Crystal River, Florida, which will be used as a basis for predicting the thermal pollution of water areas influenced by the cooling water discharge of a nuclear power plant. The surface temperature data will be collected using CAL'S Piper Aztec Aircraft equipped with a Barnes PRT-5 radiation thermometer (radiometer) and a camera system. The axis of the cameras and the radiometer are aligned so that the photographs, which are taken simultaneously with the radiometric data, can be used to locate the positions of the temperature data points. Two surveys, each consisting of about four flights, will be conducted. Maps containing contours of equal surface temperature will be prepared. The program was initiated April 4, 1969 and is scheduled for completion by October 1, 1969.

SUPPORTED BY Florida Power Corporation

2.0686, EVALUATION OF SOME ENVIRONMENTAL CONDITIONS CAUSING ALGAL BLOOMS
S. AARONSON, City University of New York, School of Liberal Arts, *Flushing, New York* 11367

2. WATER QUALITY

The secretion by algae of large quantities of cellular metabolites into the environment will be examined. Two principal methods will be employed to evaluate the accumulation of metabolites and secretory ability: (1) The olive-green chrysomonad, 'Ochromonas danica', will serve as a model organism for determining the conditions of growth and stress which lead to the accumulation of micromolecules (amino acids, nucleic acid constituents, sugars, etc.), macromolecules (proteins, polysaccharides, enzymes, RNA, DNA), and membranous vesicles and (2) Inhibitory concentrations of metabolite analogs will be used to select (a) for algae which can synthesize large quantities of target metabolite and (b) against specific algal groups.

SUPPORTED BY U.S. National Science Foundation

2.0687, TAXONOMY AND ECOLOGY OF AQUATIC PLANTS, FIELD AND CULTURE STUDIES
H.S. FOREST, State University of New York, Graduate School, *Geneseo, New York* 14454

These activities continue with some changes in emphasis: 1) Reference herbaria of aquatic angiosperms and algae, 2) Taxonomic review of aquatic plants (emphasis on Western New York), 3) Studies on environment of Conesus Lake with particular view to its value as a model for problems in phosphate fertilization of lakes, 4) Identification and reclassification of algae in principal culture collections of world, 5) Projector slide library for identification of algal species (expansion and availability as professional resource), and 6) Training in aquatic plant taxonomy and ecology.

During 1969-70 a land utilization study for the Conesus Basin was completed. This includes some comparison of on-ground information with that retrieved from the photograph-computer system maintained at Cornell University. Lake studies were intensified around the mouth of Wilkins Creek, bearing municipal sewage effluent with the objective of obtaining base data for the condition of the area before removal of the effluent to a treatment plant (1972?). Activity was extended to Canandaigua Lake for preliminary assessment of the effect of effluent from a proposed high-density development near the mouth of Seneca Creek, and during the summer of 1970 a study of two input streams, Naples Creek and West River, will be conducted to provide further information on their condition and their probable effect on the quality of water in the lake.

Cooperative studies were initiated on bottom sediments of Conesus Lake by members of the Earth Sciences Department of the College.

The majority of the studies will be conducted in the Geneseo, New York vicinity. The project began Jan. 1968 and will conclude June 30, 1971.

SUPPORTED BY New York State Government - Albany

2.0688, FEASIBILITY OF A MOBILE SUBMERSIBLE FOR USE IN CONTROL, MANAGEMENT, STUDY OF NATURAL PROCESSES, PROTECTION & CONSERVATION OF INLAND WATERS
E.T. CRANCH, Cornell University, School of Engineering, *Ithaca, New York* 14850

The proposed research project is directed toward determining the feasibility and design criteria for a mobile submersible vehicle so instrumented that it could perform the function of gathering the data base information for the following wide range of water resource needs: conservation, pollution (including thermal), limnology, ecology, natural cyclic processes, construction, control and management. Such a submersible would greatly enhance the full three-dimensional exploration of lakes and offshore ocean environments including the water-sediment interface. Contemplated is a mobile submersible which could be moved by truck from site to site.

The research project will involve determining the structural and instrumentation requirements for such a vessel and these requirements will be incorporated in an overall systems plan. The feasibility of such a submersible will be established and especially difficult constraints or knowledge gaps will be identified.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0689, FINITE ELEMENT APPROACH TO THE POLLUTION ANALYSIS OF LAKES
J.A. LIGGETT, Cornell University, School of Engineering, *Ithaca, New York* 14850

This research will apply the finite element techniques to the solution of problems related to the dynamics of lakes. The results will be applicable in particular to various pollution problems such as thermal effects and the transport and diffusion of particulate matter. In particular the research will include: 1. Integral relationships for formulation of the finite element representation of the fluid-thermal lake flow problem. 2. Transformation of the integral relationships derived in the initial step into algebraic representations for isoparametric, three dimensional elements. 3. Performance of analyses of component problems in one or two-dimensional heat transfer or fluid flow order to verify the accuracy of the solution. 4. Definition and solution of simplified one-, two, and three-dimensional lake problems which have been studied previously. 5. Definition of a plan of implementation of a full scale, highly realistic model based upon the prospective use of massive general purpose computer programs.

2.0690, A STUDY OF THE NUTRIENT INPUTS INTO CAYUGA LAKE AND SENECA LAKE
G.E. LIKENS, Cornell University, School of Biological Sciences, *Ithaca, New York* 14850

The quantitative input of various cations and anions to Cayuga Lake and Seneca Lake will be determined from routine analysis of precipitation and tributary streams. The effects of varying watershed utilization on nutrient inputs to these lakes will be evaluated. The study will provide basic data on the interrelationships between a lake and its watershed.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0691, MICROBIAL FORMATION OF POTENTIALLY HAZARDOUS ORGANO-METAL COMPOUNDS IN WATER
M. ALEXANDER, State University of New York, School of Agriculture, *Ithaca, New York* 14850

The research is designed to determine what organo-metal compounds are biologically formed in water, establish conditions for their formation and identify microorganisms responsible for the conversion. Metallic and carbonaceous compounds will be added to model aquatic ecosystems to assess the possible microbial reactions. Individual microorganisms capable of forming organo-metal compounds will be isolated, and the pathway of biosynthesis will be characterized by using these isolates. The compounds produced will be characterized by gas and thin-layer chromatography, and mass spectrometry. Particular interest will be placed on the methylation of mercury, selenium, cadmium and arsenic. The possible use of chelates as sources of metals involved in methylation reactions will also be investigated.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0692, MINERALIZATION OF ORGANIC PHOSPHORUS IN OLIGOTROPHIC LAKE SEDIMENTS
D.A. WEBSTER, State University of New York, School of Agriculture, *Ithaca, New York* 14850

The availability of sediment phosphorus in a shallow, oligotrophic lake will be increased by altering the mechanisms of inorganic phosphate fixation and stimulating microbial mineralization of organic phosphorus. These changes will be effected by raising the pH and base saturation of the sediments through lime application.

The proposed research plan will attempt to evaluate the effects of liming on the organic phosphorus in the sediments. Specifically, the following information will be sought: 1. The total organic phosphorus content of the sediments. 2. The specific organic phosphorus compounds present, as determined by chemical

fractionation, chromatography, and enzyme assay. 3. The origin and stability of these compounds in the sediments. 4. The solubility and hence, availability of these compounds as substrates for enzyme reactions. The effect of pH, calcium, iron, and aluminum are specific factors involved. 5. A comparison of rates of hydrolysis, before and after treatment. 6. An evaluation of the significance of the organic phosphates and their products to the phosphate metabolism of the lake.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0693, MODELING THE FUNCTIONAL RELATIONSHIPS WITHIN SALT MARSH EPIPHYTIC COMMUNITIES
J.J. LEE, City University of New York, School of Liberal Arts, *New York, New York* 10031

This study involves the development of mathematical models of microcosms which can be used as tools for judging water quality in inshore salt-marsh environments in the Greater New York City area. These mathematical models are based upon data previously obtained from ecological studies of marsh communities, and will include populations ranging from microbes through birds, finfish, and shellfish. The data obtained will permit the definition of environmental variables which regulate community structure and succession. In many of these marsh communities these variables include domestic sewage, industrial waste, hydrocarbon pollution from airplanes and boats. Such data when converted to use in mathematical models can be used to predict changes in community structure which will result from various forms of pollution. Such information is essential in the study of significant environmental problems which loom larger each year and which require decisions with respect to the utilization and management of salt marshes near metropolitan areas.

SUPPORTED BY U.S. National Science Foundation

2.0694, STUDIES OF APPLICATIONS OF RADIOISOTOPES FOR ESTUARY POLLUTION CONTROL
M.D. DISKO, Quirk Lawler & Matusky Engrs., *New York, New York* 10017 (AT(30-1)-4120)

Dissolved oxygen concentration is used as a principal index of organic waste pollution in a waterway. The important source of replenishment of dissolved oxygen is the reaeration or transfer of atmospheric oxygen into the waterway. Basic studies in the pollution control field have resulted in a fundamental relationship for reaeration prediction in non-tidal rivers. In estuaries and tidal rivers, the reaeration transfer is calculated by the difference in a material balance. Practical problems of measurement of flow, dispersion, biochemical reactions, etc., place the validity of the calculated estuarine reaeration in considerable doubt.

Investigations by the United States Public Health Service (Tsivoglou) have resulted in a technique for in-situ measurement of reaeration using krypton and tritium. However, additional work must be performed to adapt the Tsivoglou technique to tidal rivers and estuaries. A prime objective of the project is the development and demonstration of equipment and techniques for direct measurement of reaeration, using radioisotopes, in tidal rivers and estuaries. Data obtained for various tidal and meteorological conditions will be used in the development of an analytical expression to predict oxygen transfer in tidal rivers and estuaries.

SUPPORTED BY U.S. Atomic Energy Commission

2.0695, RIVER ESTUARY POLLUTION CONTROL STUDIES WITH RADIOISOTOPES
J.P. LAWLER, Quirk Lawler & Matusky Engrs., *New York, New York* 10017

The project is to develop and apply radioisotope methodology in river/estuary pollution control studies. Specific efforts are being made to develop routine methods for (1) longitudinal dispersion (2) reaeration and (3) flow attenuation measurements. For the dispersion and flow attenuation studies, the radioisotope technique will be specifically compared with dyes. However, radioisotopes provide the only means for direct determination of reaeration. For reaeration, several of the radioactive rare gases will be studied in combination with Tritium.

SUPPORTED BY U.S. Atomic Energy Commission

2.0696, ENTEROVIRUSES IN DEPURATED HARD CLAMS, 'MERCENARIA MERCENARIA'
G. STROBEL, State Div. of Fish & Game, *Oakdale, New York* 11779

The purpose of this phase is: 1) To survey hard clams from moderately polluted waters of Long Island for enteroviruses (Polio Types I, II, and III; Coxsackie B Types; ECHO). 2) To observe release rate of enteroviruses in hard clams during the depuration process, and thus obtain information on the efficacy of the process for virus removal.

Samples will be collected from the Depuration Plant, West Sayville, New York and examined for the presence of viruses in the Department of Biology, State University of New York at Stoney Brook, New York.

Hard clam samples will be homogenized and rendered bacteriologically sterile with antibiotics and high speed centrifugation. Viruses will be detected using an indicator system of commercially purchased Rhesus monkey kidney monolayer cell culture tubes. Inoculated tubes will be observed during 10-14 days incubation for viral cytopathogenic effects.

Release data will be evaluated in conjunction with the bacterial studies to determine if any correlation exists between the bacterial release rates and the viral release rates.

Work will commence immediately and continue for the duration of the project.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish.

2.0697, MONITORING WATER EFFLUENTS FROM A NUCLEAR POWER PLANT
E.E. CHERMACK, State University of New York, Graduate School, *Oswego, New York* 13126

A study of the thermal characteristics of the waters of Lake Ontario near East Nine Mile Point (Mexico Bay) be undertaken in order to detect the distribution of heated effluent from a nuclear power plant in the area. The degree of change in the thermal structure of the lake in the Nine Mile Point area will help determine the extent to which such a heated effluent need be considered as a serious meteorological or ecological factor. An extensive measurement program, including both surface temperature and temperature profiles before and after plant operations are started is suggested.

This project is being carried on under the auspices of the Lake Ontario Environmental Laboratory (LOTEL) of the State University of New York, College at Oswego.

SUPPORTED BY State University of New York - Albany

2.0698, GEOCHEMICAL STUDIES OF CONTINENTAL WATERS
W.S. BROECKER, Columbia University, Lamont Doherty Geolog. Observ., *Palisades, New York* 10964 (AT(30-1)-2493)

The research carried out under this contract is aimed at understanding interactions of sediment, water and atmosphere. The major categories of research include: (a) gas exchange studies to understand mechanisms of air-water interactions, and the role that pollution may play in affecting exchange; (b) geochemical cycles in closed basin lakes, which will aid in understanding how processes of sedimentation affect the chemistry of the remaining waters; (c) chemical processes in weathering and soil development, to better understand the origin of detrital minerals, and factors affecting the chemical nature of soils; (d) thermodynamics and kinetics of low temperature processes. Development of theoretical models to explain phenomena observed in the various studies mentioned above.

Chemical tools used in these studies include measurement of H,C, and O isotopes, radioactive nuclides C-14, H-3, Sr-90, Cs-137, Rn-222, and U and Th daughter products, measurement of concentrations and activities of major and trace elements and of gases (pCO_2, pO_2, etc.) as well as pH and Eh of the solutions, and mineralogical determinations of the sediments.

2. WATER QUALITY

2.0699, GEOCHEMICAL OCEAN PROGRAM - CAPITAL EQUIPMENT FOR ANALYTICAL WORK AT SEA AND AT LAMONT

W.S. BROECKER, Columbia University, Lamont Doherty Geolog. Observ., *Palisades, New York* 10964

Considering the ocean as a source of food, a disposal area for nuclear and industrial waste products, and a controlling factor in the earth's climatic regime, our ultimate use of the sea is critically dependent on a detailed understanding of processes presently understood in only the vaguest and most qualitative way. These are the stirring and mixing processes in the deep sea, the interchange of material between deep and surface water, the variation of organic productivity throughout the ocean, and the exchange of water and gases with the atmosphere. The GEOSECS program will measure in detail the oceanic constituents along Arctic to Antarctic sections at all depths, to provide, for the first time, a set of physical and chemical parameters measured on the same water samples. These data will provide the input for quantitative studies of oceanic mixing and organic productivity, and, at the same time, serve as a baseline for the levels of pollutants and of fission and waste products being added to the sea. The Lamont- Doherty group will develop procedures and equipment for collection and analysis of near surface and near bottom samples for 'in situ' radon content, as well as Ra226 content of the 100 liter samples returned to laboratories, mass spectrometric procedures to measure barium content, a shipboard extraction and shore analysis system for Ra228 and Ra226 in these same samples; they will construct infrared analyzers and equilibrators for shipboard CO2 partial pressure analysis, two CO2 gas chromatographs to measure CO2 content of returned samples, develop the extraction systems for C14 and Cs137; they will develop deck handling of large-volume samples and perfect large-volume sampling bags.

SUPPORTED BY U.S. National Science Foundation

2.0700, ECOLOGY OF YEASTS IN LAKE CHAMPLAIN

W.L. COOK, State University of New York, Graduate School, *Plattsburgh, New York* 12901

The yeast population of Lake Champlain has never been determined. This makes it imperative that the normal yeast population be determined before pollution, which usually follows increasing human utilization, changes the environment. Yeasts could possibly be used as indicators of pollution.

Beginning February 1968, monthly water samples are being taken from two selected sites in Lake Champlain. Yeasts are collected with Cobet Sterile Water Samplers, concentrated with a Millipore filter, isolated and identified by standard biochemical and morphological means. The water samples are further analyzed for temperature, oxygen, carbon dioxide, alkalinity, pH and conductivity.

SUPPORTED BY State University of New York - Albany

2.0701, A LIMNOLOGICAL INVESTIGATION OF IRONDEQUOIT BAY, ROCHESTER, NEW YORK

W.H. DIMENT, Univ. of Rochester, School of Arts, *Rochester, New York* 14627

This project consists of a series of measurements to determine the characteristics of Irondequoit Bay, New York. The Bay presently serves as the prime water resource of Monroe County and recieves a significant nutrient load from the Rochester City sewage system. A sewage interceptor system is to be completed in approximately two years which will divert much of this nutrient from the Bay and should result in reducing its eutrophication. This study will provide a body of information on the Bay prior to the proposed changes.

Physical, chemical and biological measurements will be made, including analyses of all major ions and some of the more significant minor elements. The phytoplankton and microorganism populations in the Bay will be identified and geochemistry of the sediments of the Bay will be examined.

SUPPORTED BY U.S. National Science Foundation

2.0702, COMPOSITION OF RESIDUES FROM PULP BLEACHING TREATMENTS

C.W. DENCE, State University of New York, School of Forestry, *Syracuse, New York* 12224

The spent liquors from kraft chlorination and alkali extraction pulp bleaching sequences are to be examined by various chemical and physical means to determine the structure and composition of the modified liqnin residues contained therein. Special emphasis will be placed on establishing the presence or absence of o-quinone intermediates in the chlorinated pulps and in the chlorination spent liquors. This phase of study will be prefaced by a detailed study of the reactions lignin- like (model) compounds with chlorine in which attempts will be made to isolate and characterized the anticipated o- quinone intermediates. Attempts also will be made to characterize the products arising from reactions of the (proposed) o-quinone intermediates and other substances likely to be present in the bleaching system. Finally the reactivity of chlorolignin toward alkali will be examined to gain an insight into the structure of the resulting residues particularly insofar as the location of the chlorine substituents on the chlorolignin molecule is concerned.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0703, DIATOM POPULATIONS CHANGES IN LAKE GEORGE - PHASE III

N.L. CLESCERI, Rensselaer Polytechnic Inst., School of Engineering, *Troy, New York* 12181 (C-2209)

This work is designed to characterize and measure the diatom populations in the plankton and periphyton over a three year period at various depths and locations in Lake George. These biological measurements are being combined with water quality measurements at the same depths and locations to identify the causative factors for the biological changes taking place and to obtain base line data to aid in the development of an ecosystem model for the lake.

The last phase of the program (Phase III) will include enumeration and characterization of the periphyton and plankton diatoms in regions of the lake affected by nutrient input, analysis of recent sediments in these regions, and measurement of periphyton diatom reproduction rates under different environmental conditions, but will be mainly concerned with the mathematical analysis and interpretation of the data from all three phases of the program and the formulation of a diatom growth model of general applicability to northern oligotrophic-mesotrophic lakes.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0704, ORGANIC NUTRIENT FACTORS AFFECTING ALGAL GROWTH

N.L. CLESCERI, Rensselaer Polytechnic Inst., School of Engineering, *Troy, New York* 12181

The main purpose of the study is to ascertain and identify those organic compounds extant in treated secondary wastewater effluents which have an effect on algal growth.

The methodology for fractionation of wastewater chemicals by gel permeation chromatography has been developed in the first year of the project. The effect of wastewater fractions on algal growth is being studied.

The test organisms being considered are 'Selenastrum capricornutum', 'Microcystis aeruginosa', and 'Anabaena flos-aquae'. The medium for growth of algae and the method for the inoculation of these cultures will be as per the Provisional Algal Assay Procedure (1969).

The response of the test organisms to various wastewater fractions will be measured by: 1) Photosynthetic rate as a function of C14 uptake using a modification of the Goldman method. 2) Measuring growth by gravimetric or counting or nephelometric measurements.

Statistical experiment design will also be employed so as to test the synergistic effect, if any, of varying combinations of fractions.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0705, ACCUMULATION OF RADIOACTIVITY BY ORGANISMS IN EXPERIMENTAL MARINE ENVIRONMENTS
T.W. DUKE, U.S. Dept. of the Interior, Bureau of Commercial Fisheries, *Beaufort, North Carolina* 28516

The ultimate purpose of laboratory experiments on the uptake, accumulation, and retention of radionuclides from sea water by marine organisms is to collect sufficient data to be able to anticipate the dangers from any intentional or accidental pollution of an estuary or the oceans. To have some assurance that predictions concluded from results of laboratory experiments will be valid, it is necessary that laboratory data be compared with data collected as nearly as possible under field conditions. This, it is believed, can be accomplished by comparing laboratory findings with results obtained on the accumulation of radionuclides by communities of organisms held in large tanks or in ponds.

Research activities include experimentation in the laboratory and in the field. Laboratory experiments are being conducted with communities of marine organisms maintained in large tanks (1000-liter capacity) and exposed to flowing sea water containing various radionuclides including zinc-65, iron-59, iodine-131 and cesium-137. Also, a marine community composed of oysters, clams, fish, snails, crabs, algae, and marsh grass was placed in a shallow salt water pond and exposed to zinc-65 and chromium-51. Organisms, sediments, and water are being removed periodically, their radioactive content measured, and then returned to the pond. Upon completion, samples will be analyzed for total element so that the specific activity of the components in the pond can be determined. Data obtained in such experiments also will be useful in determining the trace metal requirements of various marine organisms.

SUPPORTED BY U.S. Dept. of Interior - Bu. Comm. Fish

2.0706, NATURE OF EXOTIC SUBSTANCES IN SURFACE WATERS AND IMPLICATIONS AS WATER SUPPLY CONTAMINANTS
C.M. WEISS, Univ. of North Carolina, School of Public Health, *Chapel Hill, North Carolina* 27514

The presence of exotic organic and inorganic material in surface waters, that might be used as water supplies, will be determined by the use of macro-invertebrates and periphyton as bioconcentrators. These will be collected on standard substrate collectors. The main stream of the Haw and New Hope Rivers will be compared with non-polluted tributaries using the substrate collectors as well as, for comparison, processing batch samples of water by freeze concentration cascades. Through suitable analytical procedures following sample clean up, flame ionization and electron capture detectors on gas chromatographs and atomic absorption spectrophotometry, a qualitative and quantitative assessment will be made to establish whether the presence of detected

$ substances might countervene the use of these waters as a water supply when impounded as New Hope Lake. A monthly sampling frequency for the collectors and bi-monthly for the water samples will establish seasonal patterns that may be related to agricultural activities. This project will be initiated in FY 72 with establishment of validity of procedures by FY 73.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0707, DEVELOPMENT OF PROVISIONAL ALGAL ASSAY PROCEDURE
C.M. WEISS, Univ. of North Carolina, School of Public Health, *Chapel Hill, North Carolina* 27514

The general objective is to evaluate the two techniques, batch and continuous-flow, for assaying the algae growth-nutrient concentration relationships in natural and enriched waters. To accomplish the general objective, specific objectives will be: 1. To compare the growth response of selected algae in batch and chemostat growth units as to sensitivity to concentrations of the presumed limiting nutrients (at least N and P). 2. To evaluate the growth response of selected algae in batch and chemostat growth units in accordance with current theoretical concepts describing algal growth. 3. To make a statistical evaluation of growth kinetic constants calculated from data obtained from both batch and chemostat growth units. This will allow conclusions to be made as to whether the two procedures yield comparable or significantly different results. The growth contants, K sub s (saturation coefficient), mu (maximum specific growth rate), and Y (yield coefficient) are considered most significant and sensitive and those constants will be evaluated statistically first, and possibly other parameters. 4. To determine the most accurate technique for cell mass determinations.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0708, OPERATE A NETWORK FOR THE COLLECTION OF PRECIPITATION
M. GEOGEVICH, U.S. Environ. Protection Agcy., Air Pollution Control Office, *Durham, North Carolina* 27709

Objective: Provide a network for the collection of precipitation from selected sites within the U.S. These samples can be used to determine various chemical species contained therein in order to provide information on wash-out and soil entrainment.

Approach: Precipitation is collected with automated samplers at selected sites. Six of these sites also double as part of the WMO international precipitation network.

Goal: Samples will be collected from 16 sites and submitted to the laboratory on a two week schedule as applicable.

SUPPORTED BY U.S. Environ. Protect. Agency - N.A.P.C.A.

2.0709, THE RELATION OF ESTUARINE ALGAE TO WATER QUALITY
V.J. BELLIS, East Carolina University, Graduate School, *Greenville, North Carolina* 27835

To describe spatial and temporal patterns of distribution among algae of the Pamlico River Estuary. This project will explore the computer multifactor analysis of phytoplankton data collected by the Pamlico Marine Laboratory of North Carolina State University (Project B- 004-NC). Project includes assembly of data, preparation of data matrix, analysis of data deck, clustering and interpretation.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0710, CHROMATOGRAPHIC CONCENTRATION OF PESTICIDES FROM A LARGE MASS OF WATER
T. ITO, East Carolina University, School of Arts, *Greenville, North Carolina* 27834

The objective of this research is to try to develop a more adequate than presently available method to extract and concentrate pesticides from a large mass of natural water.

Reversed-phase partition column chromatography is the method of choice to determine what specific requirements are to be satisfied to accomplish such objective.

Suitability of various types of solid supports and stationary phases will be examined to find the best condition. 'Anchored' stationary phases, which are covalently bonded to solid supports, will be prepared to determine their suitability for extraction and concentration of pesticides from a large mass of water.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0711, BIOLOGICAL MONITORING.
R.L. HOGAN, State Wildlife Resources Comm., *Raleigh, North Carolina* 27602

The initial approach towards the ultimate objective of biological monitoring will be to determine the structuring and size of small shelters that prove most attractive to resident macrobenthos and from which the organisms can be most easily recovered.

During fiscal year 1971, it is proposed to test the comparative attractivity to macrobenthos of easily dismantled cubes of masonite laminea (following the precedent of Hester and Dendy, 1962), similar cubes constructed of the plastic 'spawning matrix'

developed by the Minnesota Mining and Manufacturing Company, and cubes of other material as may be found suitable. Cubes of each type will be both suspended near the surface and anchored near the bottom at selected locations. Cubes of each type will be retrieved at intervals, dismantled, and the inhabitants recovered for both quantitative measurement and toxonomic identification to the degree necessary to permit direct comparisons of the attractivity of the matrices. Once comparative preference between matrices is established, the next exploration will concern the optimum size and location for the shelters. Initially, the comparative tests will be conducted in a small, acid-water lake, a major Piedmont River and a major Coastal river which seasonally receives intermittent pollution with stored pulp-mill wastes.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0712, EXPLORATORY STUDY OF LIMITATIONS OF BOD FOR ANIMAL WASTE EVALUATION
F.J. HUMENIK, Univ. of North Carolina, School of Agriculture, *Raleigh, North Carolina* 27607

Although the Biochemical Oxygen Demand (BOD) test is probably the most widely employed analysis for the measurement of organic pollution in terms of oxygen demand waste effluents will have upon receiving waters, it is readily acknowledged that this bio-assay is subjected to many interferences and errors. In particular, BOD values for many animal wastes are extremely variable and correspondingly misleading.

The purpose of this research is to explore the influence of dilution, toxic metals (feed additives) and antibiotics upon the BOD of effluent from animal waste lagoons. The concentrations of antibiotics in swine waste and lagoon effluent samples will be found by biological assay. The presence and concentration of toxic metals will be determined by an atomic absorption spectrophotometer. The Total Organic Carbon (TOC) and Chemical Oxygen Demand (COD) tests will be conducted on the lagoon effluent. Relationships will be developed to relate effluent temperature, antibiotic concentration, toxic metals, COD, TOC and sample dilution with the resulting BOD.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0713, ADVANCED STUDY OF COASTAL ZONE OCEANOGRAPHIC REQUIREMENTS FOR EARTH RESOURCES TECHNOLOGY SATELLITE
D.A. ADAMS, Coastal Zone Resources Corp., *Wilmington, North Carolina* 28401

Coastal Zone Resources Corporation as a subcontractor to Ocean Data Systems, Inc., is responsible for identification of significant coastal zone problems and related information needs in the areas of fisheries, transportation, pollution, and coastal oceanic phenomena.

2.0714, AUTOMATED FORECAST PROCEDURES FOR RIVER QUALITY MANAGEMENT
R.J. BOES, Ohio Riv. Val. Wat. San. Comm., *Cincinnati, Ohio* 45202

Data from 13 electronic water quality monitors along a 168-mile section of the Ohio River will be transmitted hourly to a central receiving station at ORSANCO headquarters. This data together with river flow forecasts and water-quality and waste-load information from municipal and industrial water users will be used to verify a 'dynamic' mathematical model of the segment of the river under study.

The project objectives are: (1) Continuous evaluation of the influence of wastewater discharges, storm water runoff, tributary flow and other factors on quality conditions in a river system; (2) Verification of a dynamic mathematical model relating the effects of runoff and wastewater discharges to resulting river quality conditions; (3) Continuous forecasts of river-quality changes at selected river locations; (4) Application of findings to water-quality control and water resources management.

2.0715, WATERBORNE DISEASE ETIOLOGY
S.L. CHANG, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Cincinnati, Ohio*

Objective of the project is to develop an understanding of etiological agents of waterborne disease, their source, survival and pathogenicity. Techniques of isolating pathogens from water are developed. Persistence and factors affecting survival are studied. Infective doses are determined.

A new aspect of the research is to develop methodology for use in studying the epidemiology of meningoencephalitis caused by the free- living amoeba 'Naegleria gruberi', which occurred in clusters in 4 geographic areas - Orlando, Florida; Richmond, Virginia; South Australia, and Czechoslovakia - associated with swimming in warm lakes, estuary, and indoor swimming pool. This free-living amoeba is frequently found in large numbers in sewage effluent, in polluted surface waters, in well water, and was isolated twice in outdoor swimming pools in the Cincinnati area. Hence, it is important to ascertain factors such as: Do there exist pathogenic and nonpathogenic strains? Is the brain invasion a complication of asymptomatic infection (carrier) of the nasopharyngeal region? Is there a critical density of this amoeba in water, above which infections among swimmers are more likely to occur? How to ascertain the pathogenecity status of the 'N. gruberi' strains isolated from water? Is pathogenecity of 'N. gruberi' associated with cytopathic effect on cell cultures, with growth characteristics, and fluorescent antibody pattern? The present project is to develop methods that can be used to identify these factors.

Project was started in January 1968 and will continue.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0716, IDENTIFICATION OF INDICATOR ORGANISMS FOR EVALUATION OF WATER QUALITY
E.E. GEIDREICH, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Cincinnati, Ohio* 45213

The long-range goals of this project are to develop a firm ratio between the various non-pathogenic indicator organism systems and enteric pathogens so that potential health hazards can be accurately predicted from an evaluation of the concentrations of indicator organisms. The relationship between total coliform organism density and enteric pathogen concentrations is not well-known. Because this is true, water quality evaluations by the total coliform method may be unduly restrictive. By expanding the number of indicator organisms from total coliform alone to total coliform plus fecal coliform plus fecal streptococci, and relating concentrations of these indicator organism systems to enteric pathogen content of a given water, which can be measured by newly improved techniques for enteric pathogens, a reliable ratio can be developed between indicators and pathogens. Besides widening the number of indicators available for evaluation of water quality, this project has improved the indicator organism test so that it may be carried out within one 8-hour working day. This will facilitate rapid evaluation of the potential health hazards in water used for drinking and/or recreational purposes. This project also has developed a sampling and evaluation technique for determining the enteric pathogen content of bottom muds. This project started in July 1967 and is continuing.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0717, TOXICOLOGICAL INVESTIGATIONS OF ORGANICS FOUND IN WATER SUPPLIES
R.G. TARDIFF, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Cincinnati, Ohio*

Objective of the project is to provide a toxicological base for water quality standards and water supply practices. The organic chemicals found in or proposed to be used in drinking water are subjected to toxicological testing. Recovery techniques for contaminants must be developed to provide material for animal testing. Project was started in April 1968 and will continue with minimal support.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0718, DISSOLVED INORGANIC REMOVAL BIOASSAY OF ALGAL GROWTH POTENTIAL
W.H. IRWIN, U.S. Dept. of the Interior, Federal Water Quality Admin., *Cincinnati, Ohio* 45226

A major objective of some treatment processes of wastewater is to so reduce the concentration of nitrogen and phosphorus that the medium will no longer support a luxuriant growth of algae. While it is generally thought that phosphorus is the ion that limits growth, there is evidence that other, but unknown ions or compounds may be limiting as well. It is the objective of this study to develop an empirical but standardized biological assay to determine whether an effluent has been sufficiently treated to limit the growth of algae. The approach to the development of bioassay will consist of culturing various algae species in purified cultures under controlled physical and biochemical conditions. Rate of growth and total population will be monitored by light-scattering techniques. Growth comparisons will be made of algae in the presence of 1) untreated water, 2) water treated by a tertiary process, 3) water intended to receive the effluent and, 4) various mixtures of treated and stream water. The project will consist of three distinct phases: 1) development of laboratory procedure, 2) evaluation of test under field practical usefulness and, 3) demonstration of the wide and general applicability of the test.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0719, CORRELATIONS OF BACTERIAL PATHOGEN OCCURRENCES IN WATER WITH FECAL COLIFORM DENSITY LIMITS PROPOSED FOR WATER QUALITY STANDARDS
E.E. GELDREICH, U.S. Environ. Protection Agcy., Division of Water Hygiene, *Cincinnati, Ohio* 45213

Research activities are to be directed toward the occurrence and persistence of water-borne pathogens in recreational waters of varying quality and the subsequent correlation of their frequency of occurrence with varying levels of fecal coliforms per 100 ml. This goal will necessitate development, evaluation and field test of methods for the detection and enumeration of Salmonella, Shigella, enteropathogenic E. coli, and Leptospira in polluted water. Attention is currently being directed to an investigation of the prevalence and persistence of enteropathogenic E. coli (EEC) in water. This information is necessary to evaluate the hazard involved in a wide range of natural waters representing a broad spectrum of pollution intensity.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0720, URBAN RUNOFF CHARACTERISTICS
L.M. LAUSHEY, Univ. of Cincinnati, School of Engineering, *Cincinnati, Ohio* 45221

The objective of this project is to establish a reliable methodology for the control of the magnitude, frequency, and quality of combined sewer runoff from urban watersheds. Extensive data are currently being collected from a typical urban watershed in Cincinnati, Ohio, and will be used for the verification of a mathematical model which is being basically developed by others under FWPCA. It is intended that the University of Cincinnati will verify and improve the basic mathematical model as field data become available so that it can be applied for practical usage.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0721, A SYSTEMS ANALYSIS OF THE WESTERN BASIN OF LAKE ERIE
G.P. HANNA, Ohio State University, Water Resources Center, *Columbus, Ohio* 43210

The purpose of the research is to conduct a systems analysis of the Western Basin of Lake Erie and adjacent areas that will combine on-shore economic relationships with in-lake ecological relationships. The connections are viewed in both directions. Pollutants generated by economic growth in the drainage area of the Western Basin have given rise to biological phenomena in the lake. Pollutant controls, intended to improve water quality, will impose costs on the economic community. The system that this research proposes to develop will be designed to measure the effects of abatement costs, imposed in various ways, on the affected industries, on employment in the region and on other attributes of the local economy.

The proposed research will (1) establish the economic relationships relevant to the problem and (2) integrate the results of other water resources research projects that are already under way in the area. Included in the latter are studies of pollutant effects on biological processes in the lake. The system is visualized as comprised of two major subsystems, the economy of the Detroit Toledo Metropolitan Area, and the in-lake ecological subsystem; and two related subsystems, the geological effects and recreational demand. Linkages between these subsystems are envisioned as mainly the pollutants, and the resulting water quality. Special studies are proposed to determine pollutant costs and markets of the products that give rise to pollutants. Costs of municipal sewage treatment and the impact of municipal taxes are other special studies that will be investigated.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0722, A STUDY OF BIOLOGICAL SYSTEMS IN THE SCIOTO RIVER AS INDICES TO WATER QUALITY
J.H. OLIVE, Ohio State University, Graduate School, *Columbus, Ohio* 43210

The proposed research plan involves laboratory and field investigations directed toward developing biological indices to water quality conditions in the Scioto River (Ohio) basin and their application to other stream systems. A biological systems analysis approach is planned in which populations of representative organisms and communities of organisms will be intensively studied in relation to physical and chemical parameters. Species diversity indices will be developed and correlated with physical and chemical parameters.

Field investigations will involve: (1) Establishment of study stations in the Scioto River above and below present and anticipated zones of water quality influence. (2) Collection at two-week to four- week intervals of biological organisms in representative habitats. (3) Collection of water and soil samples at locations described in (2).

Laboratory investigations will include: (1) Laboratory identifications of organisms by taxonomic specialists and quantification of results. Correlations between biological organisms and physical and chemical parameters will be determined. (2) Laboratory determinations of trace elements by emission spectroscopy. (3) Species diversity indices will be derived by formulas developed by Patten (1962). (4) Field determinations of chemical conditions for alkalinity, dissolved oxygen, carbon dioxide, chlorides, iron, nitrates, phosphates, silicates, and sulfates.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0723, INFLUENCE OF SUSPENDED MICROSCOPIC SUBSTANCES ON THE METABOLISM OF MICROORGANISMS RESPONSIBLE FOR BIOLOGICAL ENRICHMENT OF WATER
R.M. PFISTER, Ohio State University, Graduate School, *Columbus, Ohio* 43210

The proposed investigation is to study the interaction of environmental contaminants (defined as substances not formed biologically or naturally, and which are not normally indigenous to the water) on the microbial portion of the ecosystem. The particulate materials (detritus) will be examined on a physical, chemical, and biological basis, and the materials will be characterized using differential and gradient centrifugation in conjunction with electron microscopy. The characteristic fractions of suspended particulate material will ultimately be examined for ability to influence biological reactions. This particulate fraction of water is important to microbial relationships in the area of interfaces and biological activity. It is known that particles and molecules in solution accumulate at interfaces (this includes chemicals which can either act favorably (e.g., nutrients) or unfavorably (e.g., pesticides) to organisms) and that enzymatic reactions are concentrated at membranous surfaces. Therefore, it is of significant importance to study the capabilities of non-

biologicals that commonly end up in the waters on such colloidal or molecular interfacial systems.

The investigation will be confined to a small river or creek basin which enters into Lake Erie, and to the lake itself.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0724, THE ECOLOGIC IMPACT OF THE INTERACTIONS AMONG MICROORGANISMS AND AQUATIC CONTAMINANTS IN LAKE ERIE

R.M. PFISTER, Ohio State University, Graduate School, *Columbus, Ohio* 43210

Particulate matter in Lake Erie water will be examined on a physical, chemical, and biological basis, and this matter will be characterized using density gradient centrifugation, electron microscopy, and certain chemical analyses. Microbial portions of the Lake Erie ecosystem will be characterized on the basis of physiological types (not identification). Primary productivity, chlorophyll distribution and photosynthesis-pigment relationships will be examined to obtain information pertinent to particulate and bacterial interactions. Algae will be collected and treated to remove physically associated bacteria. Cultures of bacteria obtained from the algae will be examined in the same manner (e.g., determine physiological types) as the non-algal associated bacteria in water. Surface tension and water content of selected chemicals will be experimentally altered to study the effects on microbial populations (physiological types) and on types of particulates found in the water. Data from these experiments will be correlated in an attempt to establish cause-and-effect relationships.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0725, CHEMICAL AND SEDIMENT MOVEMENT FROM AGRICULTURAL LAND TO LAKE ERIE

G.O. SCHWAB, Ohio State University, School of Agriculture, *Columbus, Ohio* 43210

Water samples were collected and analyzed from four 1/2-acre field plots near Sandusky, Ohio. Tile effluent was collected from two plots and surface runoff from the remaining two plots. Half of the plots are farmed with conventional tillage and the other half receive no tillage. Higher than average fertilizer rates were applied and all plots received two 3-inch irrigations. Water samples have been analyzed for 11 plant nutrients, sediment, pH, BOD, COD, electrical conductivity, atrazine, aldrine, heptachlor, and paraquat. Soil samples have also been analyzed for plant nutrients and pesticide residues. Special proportional water samplers were designed and installed early in 1970. Field facilities have been modified to permit sampling during the winter season. Laboratory studies have been started with the soil from the field plots and other areas to measure phosphorous movements. Special techniques have been developed to measure phosphorous diffusion constants which will supplement the teaching studies. Leaching studies are being conducted with rain simulation equipment. Anaylses of soil and water are being completed and the data are in process of being evaluated for 1970.

SUPPORTED BY Ohio State University

2.0726, CLADOPHORA AS RELATED TO POLLUTION IN WESTERN LAKE ERIE

C.E. TAFT, Ohio State University, Graduate School, *Columbus, Ohio* 43210

The proposed research involves mapping and quantitative studies of attached Cladophora along the shorelines and on shoals adjacent to the Lake Erie Islands, and of the detached Cladophora beds that drift across the lake bottom. The approach will determine the quantity of Cladophora on the basis of dry weight, its periodicity, the chemical composition relative to that of the lake water, and the relationship of Cladophora to oxygen concentrations over the beds. Studies to evaluate harvested Cladophora as special products such as fibrous filter material, food, and/or as a mulch will be initiated. Field investigations include: 1) Aerial mapping of Cladophora beds. 2) Observations of periodic growth on the beds. 3) Quantitative measurements of Cladophora on attached and drifting beds. Laboratory investigations include: 1) Chemical analyses of Cladophora. 2) Chemical analysis of lake water. 3) Culture of Cladophora. 4) Suitability of Cladophora as a special filter medium. 5) Suitability of Cladophora as an animal food supplement. 6) Suitability of Cladophora as a speciality mulch.

2.0727, DETERMINATION OF TRACE METAL POLLUTANTS IN WATER RESOURCES AND STREAM SEDIMENTS

C.R. COTHERN, Univ. of Dayton, School of Arts, *Dayton, Ohio* 45409

The proposed research plan involves using the technique of X-ray fluorescence to determine the presence and amount of trace metal pollutants in water supplies, rivers and stream sediments. Also involved will be development of methods to trace the origin of pollutants and sediments. This project will yield information concerning water pollution not obtainable with previous techniques. This information along with a description of a standardized technique will be distributed to the relevant agencies and groups.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0728, A STUDY OF SELECTED SPECIFIC ION ELECTRODES, NO.II

J.M. PAPPENHAGEN, Kenyon College, Undergraduate School, *Gambier, Ohio* 43022

Research is to be conducted for the purpose of evaluating certain specific ion electrodes. The initial and primary effort will be directed toward the development of an analytical method, using the nitrate ion electrode, for the determination of nitrates in wastes and waters. Such development will consider the behavior, accuracy, precision, and sensitivity of the electrode as well as diverse ion studies and applicability of the method for the analyses of real samples. Other electrodes to be investigated, as time permits, for the purpose of determining if their usage might be applicable in wastes and waters include those for certain heavy metals such as Ag, Pb, Cu, and Cd ions.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0729, THE ALGAE AND ZOOPLANKTON OF PROTECTED AND EXPLOITED LENTIC HABITATS IN NORTHEASTERN OHIO

G.D. COOKE, Kent State University, Graduate School, *Kent, Ohio* 44240

A long-term survey of the species composition, distribution, and ecology of algae and aquatic microcrustacea in four representative bodies of water in Northeastern Ohio has been initiated. Two of the study sites (a lake and a reservoir) were selected on the basis that they have not been subjected to sewage or septic tank effluents or other pollutants, and the other two sites (strongly eutrophic lake and reservoir) were selected for comparative purposes.

The major objective is to prepare comparative species lists based on extensive seasonal collecting in pelagic and littoral areas. This information is to be compared with the ecological and cultural history of each body of water. This project is part of a larger study of the trophic typology of Ohio lakes.

SUPPORTED BY Kent State University

2.0730, A SYSTEMATIC AND ECOLOGICAL SURVEY OF THE ZOOPLANKTON AND PHYTOPLANKTON OF NORTHEASTERN OHIO GLACIAL LAKES

G.D. COOKE, Kent State University, Graduate School, *Kent, Ohio* 44240

Many glacial lakes on the Cuyahoga River Watershed (Northeastern Ohio) are subjected to intense cultural enrichment, thus providing an excellent opportunity for the comparison of lakes in various stages of eutrophication. The purposes of this project are: 1) to provide a thorough biological, chemical,

and physical description of several closely related lakes which are representative of other such lakes on the watershed, and 2) to field-test the hypothesis that eutrophication is not a process of ecological aging but actually results in an ecosystem with the properties of early successional stages. The hypothesis will be examined through comparative limnology. The lakes will be again studied intensively after the construction of a sewer line around them, thus providing a 'before-after' comparison.

SUPPORTED BY Kent State University

2.0731, A BIOLOGICAL SURVEY OF THE CUYAHOGA RIVER - LAKE LADUE TO KENT, OHIO
L.P. ORR, Kent State University, Graduate School, *Kent, Ohio* 44240

The major purpose of this research is to determine the water quality of the Cuyahoga River in northeastern Ohio from Lake LaDue in Geauga County to Kent, Ohio (Portage County). This is the only remaining segment of the Cuyahoga that has not been studied within the past three years. Water quality will be determined from fish and bottom fauna species composition and from physicochemical measurements that will include determinations of CO2 and O2 concentrations, pH, M.O. alkalinity, phenolphthalein alkalinity, nitrites, nitrates, and dissolved particulate organic matter.

Fish species collected will be compared to those collected in the same stretch of the River by Trautman in his 1925-50 studies. Of special interest will be a comparison of biological and physicochemical measurements in this study immediately below the Kent Sewage Treatment Plant with those made in a study conducted at the same station in 1966 just prior to the addition of secondary treatment facilities at this plant.

Hopefully, the data gathered in this study will serve as bench mark data in the unpolluted reaches of the River while those data made in polluted portions will be of value in assessing the severity of pollution and also the extent of recovery in areas where improvements have been made in water treatment.

SUPPORTED BY Kent State University

2.0732, FLORISTIC AND FAUNISTIC SURVEY IN THE CUYAHOGA RIVER WATERSHED
R.G. RHODES, Kent State University, Graduate School, *Kent, Ohio* 44240

The major objectives of this study are twofold. The first objective is to develop for the Ohio Biological Survey a detailed list of algal and fish species in waters of the upper Cuyahoga River Basin. The second objective is to compare floral and faunal surveys made at selected Cuyahoga River stations above and below the East Branch Reservoir. An effort will be made to detect and assess biotic changes associated with the East Branch Reservoir and with the inflow from a tributary of the Cuyahoga River. Complete physical data will be collected at each station.

This project is a part of master plan which will involve the prosecution and integration of long-term surveys of flora and fauna in this river system and determination of the effects of pollution water impoundment, and tributary inflow on the indigenous biota.

SUPPORTED BY Kent State University

2.0733, A FIVE YEAR LIMNOLOGICAL STUDY OF A NEWLY CREATED ACID MINE WATER IMPOUNDMENT
C.V. RILEY, Kent State University, Graduate School, *Kent, Ohio* 44240

A limnological study of a newly created 3.5 acid mine water impoundment is being conducted. The impoundment was created on the site of a former 'gob' waste dump and mine drainage ditch. Physico- chemical data concerning the mine drainage were collected prior to impoundment. Analyses have been continued on the impounded water, at various levels, as the waste materials were submerged. Analyses include pH, specific conductance, total acidity, total alkalinity, dissolved O2, free CO2, dissolved solids, Fe, Zn, Al, Mn, hardness, Ca, Mg. etc. Continuous monitoring of pH, D.O., solids, total alkalinity and temperature will be included.

SUPPORTED BY Kent State University

2.0734, EFFECTS OF AUGMENTED STREAM FLOW ON WATER QUALITY
D.B. BAKER, Heidelberg College, Undergraduate School, *Tiffin, Ohio* 44883

This project is designed to directly measure the effects of augmented stream flow on water quality in the Sandusky River. Special aspects of this study include the use of an upground reservoir for augmentation and the measurement of a wide variety of chemical and biological components. At present we are terminating the initial phase of the project wherein variations of water quality with flow volume are being measured prior to actual flow augmentation experiments.

During the period from July 1, 1969 through October 30, 1970, water samples were collected 4 to 5 times per week at each of 13 sampling locations within a 60 mile stretch of the river. Measurements included fecal coliform bacteria, chlorophyll a and b, suspended solids, conductivity, temperature, pH, D.O., B.O.D., ortho phosphate, total phosphate, nitrate, fluoride, alkalinity, calcium, magnesium, potassium, and sodium. Flows were determined at four of the sampling locations using U.S.G.S. wire weight gages and stage-discharge tables. Sampling and measurements have continued at a reduced level from Nov., 1969 through June, 1970.

In addition to examining water quality as a function of flow, data evaluation will include nutrients loading curves under a wide range of flow conditions and nutrient concentration - chlorophyll concentration relationships. The pre-augmentation phase of the project started in January, 1969 and will terminate in June, 1970.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0735, EFFECT OF IMPOUNDMENTS ON WATER QUALITY
W.R. DUFFER, U.S. Dept. of the Interior, Federal Water Quality Admin., *Ada, Oklahoma* 74820

The purpose of this investigation is to optimize reservoir water quality with regard to dissolved oxygen, excess nutrients, algal blooms, toxic chemicals, and releases to maintain flow and support stream life.

Pre-impoundmental data for the Arbuckle system have been collected at four stream stations since December 1965. Arbuckle reservoir was closed in January 1967, and biweekly sampling of chemical and microbiological parameters continues at pre-impoundment stations. Background data also exist on benthic macroinvertebrate population structures for these stations. The four pre-impoundment stream stations will be used to monitor water quality changes after the reservoir fills and can be used for comparison with background data collected prior to filling.

When Arbuckle Reservoir fills, sampling locations and schedules will be established for monitoring reservoir water quality changes. The immediate objective of this project is to relate biological and chemical parameters to the water quality of the reservoir by measuring the extent of their change in a relatively undisturbed system. Future studies will measure the extent of change in critical parameters in reservoir systems receiving waste materials.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0736, PIGMENT ANALYSIS FOR THE DETECTION OF ENRICHMENT
W.J. DUNLAP, U.S. Dept. of the Interior, Federal Water Quality Admin., *Ada, Oklahoma* 74820

Enrichment of surface waters by fertilizing nutrients from waste effluents and other sources is of major concern in water pollution control. Quantitative assessment of the extent and effect of enrichment is, however, very difficult by presently available methods. Previous studies have indicated that pigment compositions, particularly carotenoids-chlorophyll a ratios, of phytoplankton may vary in a regular and predictable manner with changes in nutrients present in the aquatic environment. The purpose of this research is to determine if analysis of phytoplankton pigments may be conveniently utilized for detection and evaluation of enrichment in surface waters.

2. WATER QUALITY

Current research involves development of improved methods for the qualitative and quantitative determination of phytoplankton pigments in aqueous media. Methods developed will be employed for study of the effect, under controlled environmental conditions, of single nutrients and mixtures of nutrients on pigment compositions of unialgal cultures, mixed algal cultures, and mixed bacterial-algal cultures. Emphasis will be placed on definition of pigment concentrations and ratios indicative of enrichment; possible utilization of phytoplankton pigment concentrations for prediction of impending nuisance algal blooms will also be investigated.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0737, STUDY OF MICROBIOLOGICAL-BIOCHEMICAL PHOSPHATE SORPTION MECHANISM BY ACTIVATED SLUDGE

W.J. DUNLAP, U.S. Dept. of the Interior, Federal Water Quality Admin., *Ada, Oklahoma* 74820

Study the fundamental microbiological-biochemical aspects of the sorption of orthophosphate by activated sludge. Biochemical mechanism of uptake and release of orthophosphate by mixed cultures of bacteria comprising activated sludge. Concurrently predominant species of bacteria in activated sludge of high phosphate sorbing capability will be identified. Individual species found to predominate in phosphate sorbing sludges will be subjected to metabolic studies to determine mechanism.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0738, REMOTE SENSING FOR SPECTRAL ANALYSIS OF HYDROLOGIC VARIABLES IN THE SOUTHERN PLAINS

B.J. BLANCHARD, U.S. Dept. of Agriculture, Soil & Water Cons. Res. Div., *Chickasha, Oklahoma* 73018 (SWC-023-ECH-6)

OBJECTIVE: Determine the remote sensing techniques that can be used to index hydrologic characteristics of watersheds, index and map physical characteristics of watersheds, measure pollutants and measure combinations of remote sensing data that will indicate watershed response to rainfall.

APPROACH: Collect remote sensing data over areas where extensive ground data is presently being collected and test signals for significant relationship to known measurable hydrologic data such as geology, soil moisture, soil types, soil temperature, and hydrologic condition. Remote sensing signatures related to the watershed parameters will then be tested over the instrumented watersheds under study in the Anadarko to Alex, Oklahoma study area.

PROGRESS: Preliminary data has been collected. All analysis and addition activities have been stopped - no funds available for this work.

SUPPORTED BY U.S. Dept. of Agriculture

2.0739, TIDAL FLATS IN ESTUARINE WATER QUALITY

D.A. BELLA, Oregon State University, School of Engineering, *Corvallis, Oregon* 97331

The project involves a study of estuarine water quality with emphasis on the role of the tidal flat regions. The approach being used employs feedback between finite-difference mathematical models and lab- field experiments. Significant errors found in finite-difference methods were studied during the past year and methods were developed to control these errors. A tunnel recirculating benthal respirometer is being employed to measure exchanges between tidal flat muds and the overlying water. The first year's experiments measured benthal oxygen uptakes of tidal flat muds. The past year's work also involved estuarine dispersion studies; however, emphasis will shift more toward the water quality aspects of tidal areas as this is the area in which the least amount of information is currently available.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0740, AN IMPROVED TEMPERATURE PREDICTION MODEL FOR SMALL STREAMS

G.W. BROWN, Oregon State University, School of Forestry, *Corvallis, Oregon* 97331

The real problem lies in translating research findings into less complex models that will allow field foresters to anticipate the effect of proposed clearcutting on water temperature. Only in this way will foresters be able to adjust their practices to comply with established water quality standards. A secondary benefit of such a model is that it will aid water quality control agencies in developing realistic standards.

A model such as this has been prepared from the research data previously collected. This model is currently being tested by field foresters throughout Oregon, particularly those in public agencies. After one field season's use, this first model has shown, as expected, some deficiencies. Its lack of accuracy on some streams indicates that further work will be required before a simplified 'Universal' prediction model can be derived. The model works very well on other streams, however, indicating the promise offered by this technique.

Simply stated, the objective of the proposed research is to redefine and test the temperature prediction model now in use so that it may more nearly become a universal predictor of the effect that clearcutting induces in the temperature regime of small streams.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0741, AIR PHOTO ANALYSIS OF OCEAN OUTFALL DISPERSION

F.J. BURGESS, Oregon State University, School of Engineering, *Corvallis, Oregon* 97331

The objectives of this research project are to: (a) develop photographic remote sensing methodology for the quantitative evaluation of dispersion of wastes from existing or proposed ocean outfalls and (b) relate the diffusion coefficients and plume patterns to physical oceanographic parameters. Although the investigation is limited to coastal waters, the procedures are applicable to the evaluation of waste disposal practices in estuaries, lakes and streams.

Field studies include simultaneous measurements of ocean outfalls waste plumes by aerial photography and conventional boat sampling. Three aerial cameras provide the photographic imagery for the measurement of waste concentrations, water currents, and diffusion coefficients. A densitometer converts the photography to digital data. The photographic film densities for the spectral bands are compiled and analyzed by a computerized procedure. This photographic method is evaluated by comparing the waste concentrations determined from the aerial photography with those measured by boat sampling.

Steady state diffusion coefficients are determined from the concentration within each flight while non-steady state diffusion coefficients are computed from the change in concentrations between flights over the area. Vertical concentration gradients in the waste field are estimated by comparing the light return in the near infrared band with the light return in the red band.

The research project began June 1, 1968 and will be completed December 31, 1971.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0742, GEOSECS - AUTOMATED NUTRIENT ANALYSES AND MEASUREMENT OF ORGANIC CARBON

J.V. BYRNE, Oregon State University, School of Science, *Corvallis, Oregon* 97331

Considering the ocean as a source of food, a disposal area for nuclear and industrial waste products, and a controlling factor in the earth's climatic regime, our ultimate use of the sea is critically dependent on a detailed understanding of processes presently understood in only the vaguest and most qualitative way. These are the stirring and mixing processes in the deep sea, the interchange of material between deep and surface water, the variation of organic productivity throughout the ocean, and the exchange of

water and gases with the atmosphere. The GEOSECS program will measure in detail the oceanic constituents along Arctic to Antarctic sections at all depths, to provide, for the first time, a set of physical and chemical parameters measured on the same water samples. These data will provide the input for quantitative studies of oceanic mixing and organic productivity, and, at the same time, serve as a base-line for the levels of pollutants and of fission and waste products being added to the sea. Oregon State University will develop and test for nutrient and dissolved organic carbon (D.O.C.) analytical systems capable of obtaining precise nutrient and D.O.C. data necessary to understand the basic nutrient budget. With the aid of oxygen, carbon dioxide, alkalinity, and pH data, they will realistically assess the oxidative and preformed nutrient concentrations, the preformed nutrient data to be used for water mass characterization.

2.0743, A PRELIMINARY BASELINE STUDY OF DILUTED POLLUTANTS IN THE PACIFIC OCEAN

N. CUTSHALL, Oregon State University, School of Science, *Corvallis, Oregon* 97331

This program is composed of three identifiable efforts as follows: (a) Samples from the ocean including zooplankton, squid, and fish will be analyzed for pollutants (heavy and transition metals, chlorinated hydrocarbons and polychlorinated biphenyls). The samples will be from suitable existing collections and from transects across the Pacific (southwest to northeast) during 1971. (b) Similar measurements will be made on samples from coastal waters (Mexico to Washington and north) to define distribution of pollutants in the food chain, sediments, and suspected source areas. (c) The results of those measurements will be studied by an interdisciplinary group of West Coast oceanographers, later meeting with a similar East Coast study group to design a scientific plan for a long-term research effort in the Environmental Quality of the Oceans.

2.0744, A CLASSIFICATION OF THE LAKES OF THE STATE OF OREGON

J.R. DONALDSON, Oregon State University, School of Agriculture, *Corvallis, Oregon* 97331

The primary objective of the proposed research is to continue to make an accurate appraisal of the quantity and quality of the lakes of the state of Oregon in order to document for posterity the existing conditions and to serve as an aid to the present and future water use manipulations.

The specific project objectives are as follows: (1) Assemble information presently available concerning the lakes of Oregon. (2) Continue to sample selected lakes by differing geological areas and/or drainage basins in order to accumulate limnological data essential for a statewide classification. (3) Set up a format for recording and processing the collected information with the eventual purpose of making the results available in published form.

The field work involves the collection of information on the morphological (dissolved oxygen, pH, alkalinity, major cations, total solids and specific conductivity) and the qualitative and quantitative aspects of the biota of each lake visited.

An intensive study of four oligotrophic lakes (Crater, Woahink, Odell and Waldo) was begun in June, 1968. Routine limnological and basic environmental data is being assembled and compared. Phytoplankton primary production is being estimated for each lake employing the carbon-14 in situ technique. During the summer and autumn of 1969, nutrient limiting factors relative to phytoplankton will be evaluated using an in situ bioassay technique. Hopefully, this research will provide a more precise set of criteria for decribing oligotrophic lakes and predicting the future of lakes in general.

2.0745, STUDY OF AN UNSPOILED ESTUARY

B. GLENNE, Oregon State University, School of Engineering, *Corvallis, Oregon* 97331

The objective is to conduct a detailed study of Netarts Bay to develop guidelines for sound management of water quality and wise development of an essentially 'unspoiled' estuary. The Bay is one of the few estuaries on the Oregon coast which has not been touched yet by industrial activities, pollution, or shoreline development.

Basic studies have been initiated on water quality, flushing of the bay by the tides, mixing of salt and fresh water, properties of the mud flats, and the likely effects of discharging treated sewage or other wastes into the 5-mile long bay. Tide recorders have been put in selected locations to monitor water movement and elevation and to check the 'choking' of water in the entrance of the bay.

The mud flats which show during low tide are under study as are the streams which feed into the bay and the conditions which help or hinder growth of marine life.

2.0746, EFFECTS OF WATERSHED PRACTICES ON STREAMS

J.T. KRYGIER, Oregon State University, School of Forestry, *Corvallis, Oregon* 97331 (ORE-F-00803)

OBJECTIVE: Determine effects of logging and road building on stream temperature and sedimentation; predict water temperature changes associated with cover type and vegetational density along streams.

APPROACH: Temperature change in streams will be continuously monitored with thermographs established in three large watersheds. Sedimentation will be measured at the outlet of eight watersheds with DH-48 hand samplers. Data will be collected for several years before and after logging. The watersheds will be logged in 1966. Prediction equations for water temperature changes will be based on heat budgets along several stretches of the experimental streams.

PROGRESS: Temperature prediction studies have continued. Additional work to determine the rate of heated water as it moves into shade has just been completed in the North Umpqua Basin. A device for spatially integrating solar radiation beneath a forest canopy was developed as part of this study.

SUPPORTED BY Oregon State Government

2.0747, PHYSIOLOGICAL ECOLOGY OF BENTHIC ALGAL COMMUNITIES IN STREAMS AND ESTUARIES OF OREGON

C.D. MCINTIRE, Oregon State University, Agricultural Experiment Sta., *Corvallis, Oregon* 97331 (ORE00871)

OBJECTIVE: Determine, through physiological and ecological studies in the laboratory and field, the extent to which various environmental factors influence the vertical, horizontal, and seasonal distribution and abundance of attached algae in selected streams and estuaries in Oregon.

APPROACH: Conduct a taxonomic survey of lotic algae; quantify seasonal changes in species composition and diversity at selected field stations; relate productivity and community structure to environmental factors in controlled, laboratory ecosystems; relate the dynamics of communities of attached algae to the distribution and abundance of consumer organisms; determine what changes in the algal communities would have predictive value or could be used as bioindicators of water quality.

PROGRESS: Progress in the Laboratory: An analysis of the fatty acid composition of algal communities developed at different light intensities and current velocities in laboratory streams was completed. These data indicated an inverse relationship between fatty acid redundancy and species diversity. Some effects of light intensity, exposure to desiccation, salinity, and temperature on the growth and vertical distribution of marine benthic diatoms in a laboratory model ecosystem were determined. These variables had a significant effect on the species composition of the diatom flora, and biomass accumulated most rapidly on substrates subjected to high light intensities, without exposure to desiccation. Progress in the Field: A study of the diversity and similarity of diatom communities collected at seven stations in Yaquina Estuary was initiated. Results of an analysis of data obtained during August 1968 indicated that diatom diversity was higher in

brackish water than at the stations in the lower bay. A regression analysis indicated that mean salinity, salinity range, and competitive interactions with macroalgae were important factors affecting diatom diversity.

2.0748, STUDIES ON AQUATIC MYXOBACTERIA
R.E. PACHA, Oregon State University, Graduate School, *Corvallis, Oregon* 97331

Ecological studies are being carried out to determine the role and activities of myxobacteria in the freshwater environment. In particular it is of interest to ascertain the importance of these organisms in the decomposition of pollutional materials and their possible application in water quality surveillance and stream purification. Surveys of a number of streams receiving various types of pollutants are in progress to obtain information on the occurrence and distribution of myxobacteria in these habitats. The effects of environmental parameters on the myxobacterial population of water are being considered as well as the interrelationships between myxobacteria and other microorganisms present in water.

Taxonomic studies on a number of myxobacteria isolated from the aquatic habitat are in progress to permit qualitative determinations to be made on the myxobacterial flora of water. Additional studies on the nutrition and physiology of selected myxobacterial isolates are planned in order to obtain more basic information on this group of microorganisms.

2.0749, MOVEMENT OF RADIONUCLIDES IN THE COLUMBIA RIVER ESTUARY
D.W. HUBBELL, U.S. Dept. of the Interior, Geological Survey, *Portland, Oregon* 97208

Two reaches of the Columbia River estuary have been instrumented for discharge determination. These have been calibrated by direct measurements of flow from a boat at different stages and through several tidal cycles during the last two years. The data have been fitted to a existing one dimensional mathematical model. The mathematical model has been determined to be reasonably accurate and two other reaches have been instrumented similarly. In addition water samples for salinity and other chemical characteristics and sediment content are taken during all direct discharge measurements. Gross description of radioactivity in the estuary has been obtained by a sled-mounted in situ radiation detector as well as from analyses of water and sediment samples. Data compilation and integration has been augmented by a study of typical environments such as islands, tidal flats and shorelines. The mechanics of sediment transport and deposition particularly under the influence of salinity changes and flow reversal will be studied to define empirical relations to be used in calculating sediment loads. The project was initiated in FY 1964 and all field work and data collection has been completed. Final reports will be written and project terminated in FY 1972.

2.0750, THERMAL AND INDUSTRIAL POLLUTION - DELAWARE RIVER
E.W. PARKER, Lehigh University, Graduate School, *Bethlehem, Pennsylvania* 18015

In the seven mile stretch of the Delaware River from Riegelsville, N.J. down river to Milford, N. J., there are four paper mills which produce variable discharges into the river. About half way between these two limits is a steam-electric generating station which discharges heated water from condensers. At full capacity this station is generating 134 Megawatts. This corresponds to a waste heat rejection of about 6.7 x 10 to the 8th power B.T.U. per hour.

We propose to operate automatic monitoring stations at the bridges at Riegelsville and at Milford to develop comparative data for the river above and below the areas of cited pollution. Five diagnostic parameters would be recorded: Oxygen, Turbidity, pH, Conductivity, and Temperature. Sunlight intensity at Riegelsville is useful as the primary index of photosynthesis and oxygen production. The automatic water quality monitor station at Riegelsville was developed and operated by Lehigh from 1958-61 under agreement with INCODEL. We also developed a portable monitor station which records the five parameters.

The Del. Riv. Basin Comm. has succeeded INCODEL in ownership of the monitor equipment. DRBC plans to reactivate the Riegelsville Monitor Station and to let us use the portable monitor station for this proposed research.

In addition to collection of information by automatic intrumental methods we would employ standard field sampling methods such as: a. Collection of microscopic plants and animals by Millipore filter and immerser slide techniques; b. Observation of macroinvertebrates and determination of distributions in terms of types and relative abundance; c. Observation of distributions and types of rooted aquatic plants and algae; d. Measurement of Temperature and Sampling for B.O.D., C.O.D. and bacteriological counts.

2.0751, CHARACTERISTICS OF DRAINAGE FROM DEEP BITUMINOUS COAL MINES IN WESTERN PENNSYLVANIA
G.H. EMRICH, State Bur. of Sanitary Engin., *Harrisburg, Pennsylvania* 17105

The chemical characteristics of drainage from coal mines vary throughout western Pennsylvania. These characteristics must be known prior to mining in order to design and build waste-treatment facilities.

All recent data on deep mine drainage that were contained in files of Pennsylvania Department of Health were sorted and analyzed according to coal seams and to active and inactive mines. The gross character of the drainage from each seam was plotted by county and related to the geology. Chemical characteristics of drainage for each seam were summarized.

SUPPORTED BY Pennsylvania State Government

2.0752, ESTIMATING ACID MINE DRAINAGE POTENTIAL FROM COAL BEDS BY USE OF THE SOXHLET EXTRACTOR
G.H. EMRICH, State Dept. of Health, *Harrisburg, Pennsylvania* 17120

Acid mine drainage degrades many miles of streams in the coal mining regions of the United States. In order to properly design treatment facilities for acid mine drainage, the character of the mine drainage must be known before mining begins.

While many tests have been proposed, very few, if any, reproduce the natural conditions that produce acid mine drainage which this study will do. The study uses a Soxhlet Extractor packed with inert material and crushed coal. Distilled water is passed over the coal sample which is constantly being aerated. When the Soxhlet Extractor is filled with water, the water siphons back through a flask and is recirculated through the coal again. After four complete passes the fluids are analyzed for acidity or alkalinity, sulfate and iron. This is continued for a sufficient number of passes until the character of the mine drainage can be estimated. Preliminary results show close correlation of drainage from existing coal mines and estimated character of mine drainage.

Continuing research will also be performed to evaluate the effects of temperature, bacteria and sample size.

SUPPORTED BY Pennsylvania State Government

2.0753, HYDROGEOLOGY OF PUBLIC GROUND WATER SUPPLIES IN PENNSYLVANIA
G.H. EMRICH, State Dept. of Health, *Harrisburg, Pennsylvania* 17120

This study will critically evaluate the ground water yields and chemistry of the ground water from all public ground water supplies in the Commonwealth of Pennsylvania. The information in the files of the Pennsylvania Department of Health has been compiled in a readily usable form. Work is done cooperatively with the regional staff of the Pennsylvania Bureau of Sanitary En-

gineering,State Geologist, the U.S. Geological Survey. All public water supplies using ground water sources in Pa. have been included and the data has been coded for computer analysis. Analytical programs are being developed. The data will be analyzed in order to categorize the yields and the water chemistry of ground water for each hydrostratigraphic unit. Trends in water chemistry changes will be monitored to provide information for water management programs and specific programs to abate ground water pollution.

SUPPORTED BY Pennsylvania State Government

2.0754, PREDICTION OF WATER QUALITY CHANGE IN A STREAM DUE TO HIGHWAY CONSTRUCTION ON THE DRAINAGE BASIN
L.M. YOUNKIN, Bucknell University, School of Engineering, *Lewisburg, Pennsylvania* 17837 (2R23202669)

A method is being developed for predicting water quality change in a stream due to highway construction on the drainage basin. Data are being collected on two local basins. Construction is essentially complete on the first, with the study continuing through a stabilization period. Completion is expected on the second by the summer of 1971. Hydrologic studies include precipitation, stream discharge, sediment concentrations, and soil moisture. Data describing processes and phases of construction, exposed soil characteristics, and down slope ground surface conditions are being collected.

Document provided to SIE by the Highway Research Information Service.

2.0755, UPPER DELAWARE RIVER PLANKTON STUDY
R. PATRICK, Acad. of Nat. Sci. of Phila., *Philadelphia, Pennsylvania* 19103

The purpose of this study is to provide for a program of comprehensive research to determine the type and density of plankton organisms present, the conditions which control their growth and survival on the main stream of the Delaware River between Trenton and Tocks Island and the effects of plankton on taste, odor, and other water quality problems. Field work will include net and diatometer sampling at a number of key stations along the river.

SUPPORTED BY Delaware River Basin Comm. - Washington

2.0756, BACTERIAL GROWTH AND THE DELAWARE ESTUARY MODEL
E.R. GLASER, Drexel University, School of Engineering, *Philadelphia, Pennsylvania* 19104

Equations describing the growth rate of aerobic bacteria and also equations specifically for the enterococci and total coliform bacteria will be added to the model and simulation developed by the Delaware Estuary Comprehensive Study. The proposed model will be useful in predicting bacterial concentrations for expected improvements in estuarine water quality parameters. This will be a valuable tool in planning for water-contact recreation on the estuary.

SUPPORTED BY U.S. National Science Foundation

2.0757, QUANTITATIVE METHODS FOR PESTICIDES IN NATURAL WATERS
I.H. SUFFET, Drexel University, Graduate School, *Philadelphia, Pennsylvania* 19140

The long-term objective of this study is to develop reproducible quantitative analytical techniques for organophosphate and carbamate pesticides in natural waters. These objectives can be fulfilled by the development of the most efficient liquid-liquid extraction and cleanup procedures.

The best analytical conditions for liquid-liquid extraction and cleanup should be based upon thermodynamic data. Presently, the choice of extraction parameters is based upon the criteria of intuition which is then followed by empirical trial and error analysis. This study will attempt to develop thermodynamic data based upon the partition coefficient expressed as a p-value so that a rational choice of extraction parameters can be made for different natural waters.

The primary goal of the study will be directed toward the analysis of the capability of the p-value for rational choice of extraction parameters in different types of natural waters; a clean low turbidity type, a polluted high turbidity type, and a high dissolved solids type. The extraction parameters obtained then will be evaluated in terms of the concentrations found in natural waters. As necessary, cleanup of natural water extracts will also be guided by p-values between immiscible solvents.

The determination of the p-values for organic pesticides will enable a theoretical approach a) to devising quantitative multiple screening procedures for organophosphates and carbamates, b) delineating the conditions to avoid cleanup problems for quantitative analysis of these pesticides in natural waters and c) devising quantitative cleanup procedures for these pesticides.

2.0758, EVALUATION OF PYRITIC OXIDATION BY NUCLEAR METHODS
R.A. BAKER, Carnegie Mellon University, Graduate School, *Pittsburgh, Pennsylvania* 15213

This project will be directed toward making use of the Mossbauer ef.. t through spectroscopically monitoring the oxidation processes taking place on iron pyritic materials during acid mine drainage formation. A specific objective is to determine the role of chemoautotrophic organisms in such oxidative mechanisms. These organisms may promote ferrous and sulfide dissolution from pyritic strata, accelerate the oxidative reaction once these ions are present in aqueous solutions or contribute by some combination of these mechanisms.

Natural and synthetic pyrites are to be exposed to carefully controlled gaseous and aqueous environments, with and without selected microorganisms. The nature and rate of reaction products are to be monitored by various chemical and biological techniques with emphasis on Mossbauer effect spectroscopy and radiochemical procedures. The oxidation mechanisms for ferrous and sulfide ions, the effect of specific and mixed chemoautotrophic organisms and the effect of pyritic properties on acid mine drainage are to be determined.

2.0759, HEAVY METALS - ENVIRONMENTAL CONTROL SYSTEMS DESIGN--FAIRBANKS PLACERS
T.D. MOORE, U.S. Dept. of the Interior, Bureau of Mines, *Pittsburgh, Pennsylvania* 15213

To design and develop costs for environmental control systems for mining permafrost, with special emphasis on such factors as thermal gradients, airflow patterns, and control of the environment for problem areas.

SUPPORTED BY U.S. Dept. of Interior - Bureau of Mines

2.0760, DETECTION AND LOCATION OF CONCEALED ABANDONED UNDERGROUND MINES AND ASSOCIATED DRAINAGE BY GEOPHYSICAL AND GEOCHEMICAL TECHNIQUES
W. FISHER, H R B Singer Incorporated, *State College, Pennsylvania* 16801

The exact location of concealed voids in abandoned coal mines is a problem resulting from over 150 years of mining. The drainage resulting from these mines has caused serious pollution problems. Without knowing the exact location of the concealed openings and the extent of the mine, the application of known abatement techniques would be impossible. Drilling is the only known method for determining the location and extent of the mine voids. This is an extremely expensive method. This project will investigate the use of the following geophysical methods: self-potential, resistivity, induced polarization, inductive, precession magnetometry, seismic refraction and reflection, infrared radiometry, gravimetry; and the following geochemical techniques: ground water analysis, surface water analysis, dye tracers and suspension tracers.

The above mentioned techniques will be applied to an area where precise mining records are available and the locations and extent of underground voids are well located. The test results will then be compared with the actual mining map.

2.0761, ENERGY EXPENDITURES FOR OSMOTIC AND IONIC REGULATION IN DAPHNIA

B.G. ANDERSON, Penn. State University, Agricultural Experiment Sta., *University Park, Pennsylvania* 16802 (PEN01742)

OBJECTIVE: Determine effects of various concentrations of salts, both singly and in combinations, on energy expenditures of Daphnia magna.

APPROACH: Daphnia are found in waters varying in salinity, both qualitatively and quantitatively, body fluid of accilimated animals is always maintained hyperosmotic to the medium. It is expected that the greater the difference between the osmotic concentration of the environmental medium and that of the body fluid, the greater will be the energy expended. Differences in specific ion concentrations are also expected to influence the energy expended. If a certain combination of ions requires the least expenditure of energy for maintenance of the hyperosmotic condition of the body fluid such a combination may prove to be optimum for other activities such as growth and reproduction and their ability to withstand adverse conditions. The information gained by this study should be especially valuable in the development of standardized culture and assay media since Daphnia have come into general use for the bioassay of pesticides in relation to water pollution.

PROGRESS: The rate of oxygen consumption of adult female Daphnia magna varies directly with the oxygen tension of the medium. The rate of oxygen consumption decreases linearly as the oxygen tension decreases from full saturation to 10-20 percent of saturation at which point it is about half that at saturation. Below 10 percent of saturation the rate drops abruptly as the oxygen tension approaches zero saturation. The overall rate of oxygen consumption is cyclical in that it increases during the instar up to the time the young are released and the animal undergoes ecdysis after which the overall rate decreases but increases again during the next instar. The overall rate increases by as much as 50 percent during the instar. The overall rate increases also from instar to instar as the animal grows older and increases in size. Neonate Daphnia pulex live longer in solutions made up of 5.54 mM NaCl, 0.25 mM KCL, 1.19 mM CaCL(2), 0.37 mM MgCL(2) buffered with 0.09 mM NaHCO(3) and 0.008 mM NaH(2)PO(4) to pH 8 than in solutions with lower or higher concentrations of these salts. Presumably the animals utilize less energy for ionic and osmotic balance at the above concentrations so that more of their available energy can be expended for other functions.

SUPPORTED BY Pennsylvania State Government

2.0762, THE BEHAVIOR OF SMALLMOUTH BASS AS RELATED TO ARTIFICIAL COVER

R.L. BUTLER, Penn. State University, State Coop. Fishery Unit, *University Park, Pennsylvania* 16802

Reason for study: Although cover is recognized necessary for the maintenance of many species, the characteristics of cover and the response of the organism to it have not been studied to any great extent. In some marginal streams the variability of cover may be the limiting factor for the bass population. If cover is a limiting factor, a species dependent upon it may have low population levels even where food is abundant. Much money has been spent on 'stream improvement' devices without knowledge of the preferences of fish for these structures. Since response to cover is a behavioral paramenter of a species, measures of it may be used for bio-assay.

Objectives: (1) To determine those components of cover that are attractive to smallmouth bass. (2) to demonstrate the effects of water velocity on the utilization of cover by smallmouth bass. (3) To test response to cover as a bio-assay for mine acid pollution.

Design of Project: An experimental stream trough will be built and placed in operation at a nearby impoundment. One fish at a time will be introduced into the stream trough and exposed to a series of cover objects designed to simulate various features of natural cover. Current velocity will be varied to determine its effect on utilization of the cover. The tests will be run in high carbonate and low carbonate water for baseline measures under unpolluted conditions. Bio-assay of mine acid water will be done at several stream sites offering various degrees of mine acid pollution.

SUPPORTED BY U.S. Dept. of Interior - Bu. Sport Fish.

2.0763, ESCHERICHIA COLI SEROTYPES IN MICROBIAL POLLUTION OF WATER

P.J. GLANTZ, Penn. State University, Inst. for Res. on Land & Water, *University Park, Pennsylvania* 16802

The variety and frequency of Escherichia coli serogroups isolated from water will be compared with those found in humans and animals. These data will then be used to determine the most important and prevalent serogroups that should be completely serotyped. An evaluation of the identity in respect to pathogenicity and virulence of the E. coli serotypes from a variety of sources will then be possible. Prevalence and survival of potential pathogens in the aquatic environment due to fecal contamination will then be determined.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0764, AN INVESTIGATION OF ACID MINE DRAINAGE CHEMICAL POLLUTANTS USING LASER-RAMAN AND INFRARED SPECTROSCOPIES

T.V. LONG, Penn. State University, Inst. for Res. on Land & Water, *University Park, Pennsylvania* 16802

Laser-Raman and infrared spectroscopies will be used to investigate aqueous solutions containing chemical pollutants important in acid mine drainage, which includes the soluble products of Fe (III) hydrolysis, sulfuric acid and other sulfur-containing species. Spectra of solid ferric oxy-hydroxide hydrates will also be measured, and the structures of the polymeric solution moieties will be determined by comparison with these solids and through standard vibrational techniques. A specification of the environment in which acid waters are formed in terms of participating chemical species will be attempted. The solution chemistries of other metal ions (aluminum, zinc, manganese, chromium) whose hydrolytic equilibria are fundamentally relevant in natural water equilibria, including metal ion control, soil fertility, and treatment of water for public utilization, will also be studied. The primary goal of this investigation will be to delineate the major solute species present as a function of metal ion concentration and acidity. The possible importance of photochemical reactions in hydrolytic phenomena may also be investigated using laser radiation as the source of photochemical excitation.

SUPPORTED BY Pennsylvania State University

2.0765, DETECTION OF NUTRIENT LIMITATIONS OF ALGAL GROWTH IN SURFACE WATERS

A.J. MCDONNELL, Penn. State University, School of Engineering, *University Park, Pennsylvania* 16802

The study is developing and testing the utility of using enzymatic analyses as well as ammonium absorption and respiratory responses to define the availability of nitrogen and phosphorus for algal growth in eutrophic and oliogotrophic waters. Laboratory evaluations include: 1. Tests for alkaline phosphatase activity in selected algal species. 2. Extraction of surplus-stored cell phosphorus. 3. Measurements of ammonium uptake by selected algal species sampled under different environments of nitrogen deficiency. 4. Tissue analyses for total nitrogen and phosphorus. Correlations are being made with productivity estimates, and water quality analyses for a variety of waters with a wide range of fertility.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0766, CHEMO-DYNAMICS OF LIMESTONE GROUNDWATER

W.B. WHITE, Penn. State University, Inst. for Res. on Land & Water, *University Park, Pennsylvania* 16802

Water resource management and pollution control of carbonate groundwaters requires a much more detailed knowledge of the mechanics of water movement and the chemistry of water-rock interactions than is presently available. This study is part of a long term program to understand the mechanisms by which carbonate aquifers become modified by solution and the mechanisms of groundwater movement.

An effect of flow dynamics on the empirical rate of solution for carbonate rocks will be determined by a laboratory model. This model is designed to give actual rate constants and perhaps some insight into the rate-controlling processes (which can then be used to check several theories of solution kinetics now in the literature). Flow regimes will range from laminar, through turbulent with a laminar sub- layer, to totally rough turbulent flows. Significant changes in solution kinetics are expected at the laminar-turbulent transition.

Waters from limestone aquifers will be sampled at many points of known geological relation within the aquifer. These will be analyzed chemically for the usual carbonate variables and fitted to thermodynamic equilibrium expressions. Deviations of the waters from chemical equilibrium can be used to trace sources of these individual waters and the way in which they mix to form the main groundwater body of the aquifer.

SUPPORTED BY Pennsylvania State University

2.0767, COMPARATIVE STUDY OF THE BENTHIC MICROBIAL BIOTA IN SOME COASTAL AREAS OF PUERTO RICO

E. ANGEL, Univ. of Puerto Rico, Water Resources Research Inst., *Mayaguez, Puerto Rico*

Three marine areas of the Southwest coast of Puerto Rico supposedly affected or not by chemical or animal residues are to be studied. (1). The characteristic bacteriological biota of the neritic benthic zone is going to be studied in order to find the actual population. (2). The standard physical and chemical characteristics of sea water are going to be studied in the three different areas. (3). Comparative studies will be conducted in order to establish relations between pollution and physical change to bacterial population changes, and to establish which are the believed 'normal' bacterial population (unaffected areas) and 'abnormal' bacterial population (affected areas).

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0768, TERRESTRIAL ECOLOGY

R.G. CLEMENTS, U.S. Atomic Energy Commission, Puerto Rico Nuclear Center, *San Juan, Puerto Rico* (AT(40-1))

The present emphasis is on the hydrologic cycle, animal behavior and food web analysis. Investigations are in progress on the characterization of rainfall by storm classes. The study is designed to measure the relationship between the quantity of rainfall and the quantity of throughfall and stemflow by storm classes. Chemical analyses for major and minor elements in individual rains and associated throughfall and stemflow will be made. The purpose is to develop predictive equations for the movement of radioactive and stable isotopes via the hydrologic cycle in a tropical forest ecosystem. Tracers will be used to measure the rates, amounts and pathways in selected food chains.

RESULTS: Investigations have indicated that the movement of radioisotopes is a relatively slow process in the tropical forest under study. Measurements on fallout nuclides and tracers suggest that foliar interception and absorption is the major mode of uptake while root uptake may play a minor role under undisturbed conditions. However, recent studies on 3 year old Cs134 plots suggest that disturbance of the canopy results in considerable uptake by early successional species.

SUPPORTED BY U.S. Atomic Energy Commission

2.0769, THE BIOASSAY OF WATER POLLUTANTS WITH CULTURED MAMMALIAN CELLS

H.W. FISHER, Univ. of Rhode Island, Graduate School, *Kingston, Rhode Island* 02881

In the present study we are determining the titration endpoints of toxicity of water pollutants by quantitative determinations with mammalian cells cultured in vitro. The research plan proposes to extend this study in two ways. In the first series of experiments, the plating efficiency and growth rate assays would also be carried out with a cell culture of a cold-blooded vertebrate, such as the cell line derived in 1960 by Wolf and Quimby (Science 135, 1965 (1962) from gonadal tissue of rainbow trout, Salmo gairdneri. In the second study, chromosomal analyses of cells growing in toxic concentrations of the pollutants would be carried out. Cells would be grown in concentrations of the pollutants at the threshold of toxicity as determined in our present experiments and chromosomal aberrations or changes in ploidy produced by the inorganic pollutants, herbicides, pesticides, or detergents would be documented.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0770, CRITERIA FOR RECOGNITION OF ESTUARINE WATER POLLUTION BY AERIAL REMOTE SENSING

J.F. FISHER, Univ. of Rhode Island, Graduate School, *Kingston, Rhode Island* 02881

The proposed study is to develop criteria for study of water pollution in the estuarine environment by aerial remote photographic sensing. Field confirmation of water pollutants will be related to patterns as delineated by aerial photogrammetry of an estuarine area.

Four photographic emulsions will be tested: 1. Aerial panchromatic black and white, negative. 2. Infrared black and white, negative. 3. Kodachrome color, positive. 4. Infrared ektachrome color, positive.

Five aerial photographic camera systems will be used: 1. Aerial camera, 9 x 9 inch. 2. Aerial camera, 4 x 5 inch. 3. Panoramic camera, 35 mm. 4. Motorized telephoto camera, 35 mm. 5. Telephoto camera, 16 mm.

In addition to criteria for determing water pollutants from aerial photographic sensing, recommendations will be made as to what is the most efficient and simplest camera - film emulsion system for use by local and state agencies in surveillence and study of estuarine pollution.

2.0771, THE INSECT ORDER PLECOPTERA AS A BIOLOGICAL INDEX OF FRESH WATER QUALITY

T.W. KERR, Univ. of Rhode Island, Agricultural Experiment Sta., *Kingston, Rhode Island* 02881 (RI00616-NF)

OBJECTIVE: Determine the degree of water 'pollution' on the presence of the insect order Plecoptera in a stream system in Rhode Island. The stream system will contain certain branches where type and degree of contaminants can be defined.

APPROACH: Select and map 5 sampling sites in a stream system having several branches. Sampling would be accomplished to quantify the species of Plecoptera present at each individual site. Concurrently, water samples would be taken at individual sites and bioassays undertaken to determine the percentage of organic matter, free ions, acids, etc. The 'quality' of the water including temperature/oxygen tension at each individual site would then be correlated with the number and species of Plecoptera nymphs present.

PROGRESS: Monthly determinations were made at 8 sites on the Hunt River (to July 17, 1968) of stream velocity, depth, width, bottom type, temperatures, dissolved oxygen, percent saturation of oxygen, pH, total alkalinity and carbon dioxide content. Field observations of stone fly (Plecoptera) populations were made periodically. Two species, Peltoperla (arcuata Needham?) and Taeniopteryx nivalis Fitch, predominated and in only 3 upstream, unpolluted sites. Laboratory studies were made to find the limits which nymphs could survive of dissolved oxygen, water velocity, temperature, pH, chromium and phosphates. Highway construction has changed the initial ecosystem and project.

2.0772, BAY WATCH

B. LEVINE, Univ. of Rhode Island, School of Engineering, *Kingston, Rhode Island* 02881

2. WATER QUALITY

The Bay Watch Program has a series of multiple but related goals. One is the design of a physical (and eventually a biological) monitoring system for the Rhode Island Coastal Zone. Such a system would have a variety of uses including pollution control. It is not our present intention to implement fully such a monitoring system, since this appears to be a task better suited for a state or federal agency. However, we do expect to operate a system sufficient to assist in the development and verification of the various physical and biological models previously discussed.

Our plan is to develop a limited operational capability by the summer of 1970 using standard instrumentation and processing techniques where possible in order to gain operational experience. At the same time we will be undertaking limited development work in instrumentation and data processing, these developments will be fed into the operational system as practicable. The predicted state of the bay from the analytical models will be compared with the available data and new data from the bay instrumentation system.

2.0773, SENSITIVITY OF BENTHIC MICROFLORA TO POLLUTION GRADIENTS

N. MARSHALL, Univ. of Rhode Island, Graduate School, *Kingston, Rhode Island* 02881

Recent investigations show that the major share of the high productivity of shoal estuarine environments is due to the photosynthesis of the benthic microflora. This community, composed of one-celled forms, is probably quite vulnerable to pollution. We have developed a technique for assaying the productivity of this benthic community from the C-14 uptake, using small undisturbed samples. This program, based on such assays, has the following objectives: (1) Continue to refine and verify the C-14 technique for assaying the productivity of the benthic microflora of undisturbed sediments. (2) Establish with this technique the norms for three coastal areas that are free of pollution. These observations of norms are being conducted over a three-year period to establish satisfactory base lines. One site to be studied is adjacent to the Millstone Point Nuclear Power Plant and later will be affected by 10 degree Fahrenheit temperature increase and low-level radioactive input when the plant goes active (scheduled for 1969). The other two sites are nearby estuarine areas of Point Judith Pond and the Pettaquamscutt River. (3) Investigate for a three-year period the effect of thermal change and domestic pollution on the productivity of the benthic microflora. This involves the Millstone site for thermal effects and the polluted Mystic River for effects of domestic pollution. The major microflora present and key ecological parameters are being determined for the observation sites.

2.0774, THE GAUZE PAD METHOD FOR THE ISOLATION OF VIRUSES FROM INLAND AND ESTUARINE WATERS

L.T. MILLER, Univ. of Rhode Island, School of Agriculture, *Kingston, Rhode Island* 02881

The bacterial flora of coastal and inland waters have been studied repeatedly, but information is very fragmentary concerning water pollution with human enteric viruses.

Phase 1. Evaluation and Development of Methodology. Under controlled laboratory conditions, water will be artificially polluted with known levels of enteric and other viruses. Experiments will be done to evaluate the adsorption capacity of various types of gauze pad as well as threads of synthetic fibers. Attempts will also be made to compare the elutability of virus from gauze pads of cotton and synthetic fibers in different buffers, namely phosphate, borate, tris, and others. Virus in these eluates will be concentrated by using the salts indicated above. A standard gauze pad technique will be developed for viral isolation in water and this will be used for the phase 2 study.

Phase 2. Field Investigation of Water Pollution. Samples will be collected periodically from selected areas in Rhode Island by using an appropriate standardized gauze pad technique developed in Phase 1. Attempts will be made to isolate their viral flora by inoculating the concentrates into a spectrum of cell cultures, suckling mice and avian embryos. Concomitantly, the waters for viral sampling will be tested for coliform MPN, E. coli, and fecal streptococcal contents. The viral isolation results will be correlated with those of the bacterial indicator tests.

2.0775, COLLECTION AND ESTABLISHMENT IN CULTURE OF SPECIES AND STRAINS OF MARINE PHYTOPLANKTON ORGANISMS

T.J. SMAYDA, Univ. of Rhode Island, School of Oceanography, *Kingston, Rhode Island* 02881

The University of Rhode Island Graduate School of Oceanography shall supply a large number of species and strains of marine phytoplankton which should be at the disposal of the National Marine Water Quality Laboratory, at all times, so that various environmental, physiological, and toxicological tests can be accomplished. Cultures of the various species and strains shall also be made available to other FWPCA laboratories involved in pollution control activities for use in bioassays and other tests developed by NMWQL for the detection and evaluation of pollutants. The diversity of environmental requirements of phytoplankton necessitates the establishment of individual species and strains in culture.

Further, the contractor shall develop the mechanics of a system for obtaining these organisms so that the culture collection will become complete for the purpose at hand; shall develop an orderly arrangement for accession to the collection. The contractor shall also, scientifically identify each species and/or strain of phytoplankton by established procedures; utilize as the basis for the proposed collection, organisms already being maintained by the University Laboratory, NMWQL, and those available from academic institutions and research organizations. He must further provide the NMWQL with required data, and advise the NMWQL of the progress and status of the cultures and program as requested.

2.0776, ROLE OF NEMATODES AND RELATED MEIOFAUNA AFFECTING FRESH WATER QUALITY IN RHODE ISLAND

G. STESSEL, Univ. of Rhode Island, Agricultural Experiment Sta., *Kingston, Rhode Island* 02881 (RI00615)

OBJECTIVE: Estal lish population patterns of dominant and associated nematode species in the benthos and nekton of 'unpolluted' and 'polluted' fresh waters. Study the detritus degradation of the dominant nematode species. Determine the feasibility of nematodes as biological indices of water quality when complemented with chemical indices.

APPROACH: Sediment cores and overlying water samples will be taken at monthly intervals from July, 1967 to August, 1968 at seven sampling stations along the Hunt River, Rhode Island. Sites 1, 2, 3, and 4 are upstream from industrial plants and are rural (unpolluted). Sites 5, 6, and 7 are downstream from industrial plants and in urbanized areas (polluted). The following measurements will be made and recorded on or about the 15th of each month: oxygen and temperature by means of a YSI D. O. meter; width, depth, and velocity using meter sticks and a Dutchman's log; pH using a Photovolt pH meter; and chemical measurements (PO_4), Cl, Cr, and CO_2) by standard analytical techniques. Two 24- hour surveys will be made at stations 1, 4, 5 and 6 during July, 1968. Measurements of oxygen and temperature will be made at hourly intervals using the YSI meter. Three 10 sq. cm. cores will be obtained from each of the seven stations monthly and taken to the laboratory for biological study. Nonperiodic samplings of sediments from other lakes or streams in Rhode Island will be obtained for studies of meiofauna contained in them.

PROGRESS: Core sediments were taken monthly (July, 1967 to Aug., 1968) at 4 'unpolluted' and 3 'polluted' stations on the Hunt River, R.I., and analyzed for meiofauna and nematode content and for chemical- physical parameters. Average density of populations and frequency of occurrence of meiofauna were determined over one year at the seven stations. Maximum nematode populations occurred in late winter-early spring. Dis-

solved oxygen levels, stream dimensions, phosphate and carbon dioxide levels showed no correlation with meiofauna or nematode populations. 'Polluted' sites were similar in population dynamics. Predaceous nematodes favored smaller particle size sediments, less than 50% sediment water content, and more than 12% sediment organic matter.

2.0777, ANALYTICAL PHYSICAL MODEL
F. WHITE, Univ. of Rhode Island, School of Engineering, *Kingston, Rhode Island* 02881

An analytical physical model of the Bay is being constructed. The long term objective is to produce a mathematical model which can predict hydrodynamic, thermal, salinity and oxygen changes in the Bay as a function of location and time. The analytical model of the Bay must include all types of equations, algebraic or possibly stochastic in nature, which accurately model the turbulent transport. Although there is already considerable work reported in this area, it will be necessary in Narragansett Bay to have supporting equipment to verify these models and, in the case of specific pollutants, data which refine presently proposed models. A pilot study of a three dimensional hydrodynamic model has been successfully completed for the Harbor of Refuge at Gallilee. A similar model is being constructed for Narragansett Bay and Providence River.

To assist in the development and verification of mathematical models, the 'Bay Watch' Program is developing a limited capability to measure various physical, chemical and biological parameters. For ease of operation, the majority of the initial experiments are being conducted in West Passage.

SUPPORTED BY U.S. Dept. of Commerce - N.O.A.A.

2.0778, PERIPHYTON AND PHYTOBENTHON AS INDICATORS OF WATER QUALITY
R.D. WOOD, Univ. of Rhode Island, School of Arts, *Kingston, Rhode Island* 02881

The proposed research aims to determine the effect of pollution on the attached plant growth, specifically the periphyton (--on structures or other plants) and phytobenthon (--on the bottom). The approaches are analysis of physical-chemical factors and pollution on the one hand, and periphyton-phytobenthon species and community structure on the other.

Field investigation includes study of the biota, monitoring chemical-physical factors, and sampling for pollutants: 1. Set out study areas above/below pollution effluents. 2. Monitor factors and pollutant concentration and follow plant growth throughout the year.

Laboratory work includes analysis of samples, and establishment of species and community composition of the periphyton-phytobenthon: 1. Routine analysis for factors; millipore membrane coliform count for sewage; fluorimetry for domestic wastes; and industrial tests for their wastes. 2. Identification, count, and measurement of periphyton and phytobenthon with respect to species, community structure, and biomass.

Laboratory and field data would be correlated for practical application of periphyton-phytobenthon as indicators of nature and intensity of pollution; and species data would be organized for use in related research disciplines.

2.0779, INTERCEPTION AND DEGRADATION OF PESTICIDES BY AQUATIC ALGAE
L.R. WORTHEN, Univ. of Rhode Island, School of Pharmacy, *Kingston, Rhode Island* 02881

The proposed research involves both collecting blue-green algae from several stations over a two year period and the propagation of axenic cultures of several representative species.

Those collected from natural sources will be examined to determine the extent of pesticide (DDT and dieldrin) accumulation. Radioactive isotopes of the two pesticides will be used to determine if absorption of these compounds takes place, and if these compounds are accumulated in the organism, or more important, if they are degraded and the pesticide metabolites formed.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0780, SIGNIFICANCE OF THE FECAL STREPTOCOCCI, COLIFORM BACTERIA AND COLIPHAGE IN RELATIONSHIP TO ENTERIC VIRUS POLLUTION IN SEWAGE AND RIVERS
V.J. YATES, Univ. of Rhode Island, School of Agriculture, *Kingston, Rhode Island* 02881

Due to the ease of measurement, the coliform group of bacteria have for many years been used to indicate the degree of pollution of water with wastes from human or animal sources. The limitation of such a method rests upon the fact that coliform bacteria are normal inhabitants of human or animal bodies and normally are not pathogens. So long as the rivers containing large numbers of coliform group of bacteria are condemned and cleaned, it can be said that such tests do serve their purpose. But the status of today's rivers in Rhode Island clearly indicate that many are heavily polluted with coliform bacteria; some have coliform counts equal to that of the raw sewage. Provided such an environment does exist, it is important to find out the concentration of viral contaminants.

The objective of the present proposal is to correlate the concentration of coliform bacteria, fecal streptococci, or coliphage in polluted water to viral pathogens, such as Coxsackie and poliovirus. It is hoped that a correlation can be established between the two, so that the measurement of one may provide a quantitative estimate of the other.

SUPPORTED BY U.S. Dept. of Interior - O. Wtr. Res. Rch.

2.0781, THE DEVELOPMENT OF DATA FOR BATHING BEACH CRITERIA
V.J. CABELLI, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Narragansett, Rhode Island* 02882

This study will explore the feasibility of and prepare a project proposal for an epidemiologic study to determine the relationship of illness among swimmers to the sanitary quality of the water at salt water beaches.

Following a review of the literature and criteria examination of previous studies directed at this question, a tentative experimental design will be formulated. Possible sites for the study will be screened using available information on bather density and pollution loads. Contact will be established with the public health authorities at the tentative study sites. A draft proposal for the study will be prepared and reviewed both within BWH and with the above-mentioned health authority in a series of coordination meetings. The revised proposal will be submitted for funding to the appropriate agency. Assay methods for select indicator and pathogenic bacteria are being examined.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0782, EVALUATION OF MICROBIOLOGICAL STANDARDS FOR SHELLFISH GROWING WATERS
V.J. CABELLI, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Narragansett, Rhode Island* 02882

The rationale for the project derives from the fact that at some unknown level of infectious hepatitis in the 'discharging' population, the existing microbiological, indicator standard for shellfish growing waters could be breached. Thereby, shellfish associated cases of infectious hepatitis could occur from the raw consumption of animals taken from approved waters. The documentation of this occurrence requires that 'bootlegging' and untold pollution levels due to run off and bypassing of sewage treatment facilities be eliminated as explanations for the shellfish associated cases of infectious hepatitis.

Three inputs to the study are necessary: (1) morbidity data on the overall incidence of infectious hepatitis (IH) in the area as published by NCDC, (2) epidemiologic follow-up of shellfish associated cases of IH to determine from where and when the shellfish were harvested--this is being done in Rhode Island by CDC--EIS officer--and (3) continued surveillance of the approved grow-

ing areas for untoward pollution loads as seen by excessive levels of the indicator organisms. Three requisites are needed for the study: (1) an increasing incidence of IH in the discharging population, (2) a geographic situation relative to the major sources of sanitary pollution favorable to continuous monitoring of the area and (3) a minimum of 'bootlegging.' The approved growing areas in upper Narragansett Bay in Rhode Island meet the above criteria for the study.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0783, DIRECT, LOW TEMPERATURE ENUMERATION METHODS FOR FECAL COLIFORMS IN WATER
A.P. DUFOUR, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Narragansett, Rhode Island* 02882

Methodology will be examined towards obtaining a differential and or selective procedure for the enumeration of fecal coliforms without recourse to the use of elevated incubation temperatures or certain inhibitors.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0784, QUANTITATIVE RECOVERY OF PSEUDOMONAS AERUGINOSA FROM POTABLE AND RECREATIONAL WATERS
M.A. LEVIN, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Narragansett, Rhode Island* 02882

An effort will be made to develop a quantitative method for the enumeration of Pseudomonas aeruginosa in potable waters and in fresh and estuarine waters used for recreational purposes. Emphasis will be placed on methodology which will permit the examination of relatively large volumes of water.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0785, STUDY OF GROWING AREA STANDARD BY EXAMINING ENTEROPATHOGENS AND INDICATOR LEVELS
O.C. LIU, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Narragansett, Rhode Island* 02882

The microbiological standard for shellfish growing waters (median coliform MPN is less than 70/100ml)assumes that the probability of enteric infection from the consumption of shellfish taken from the area is negligible. Validity of correlation of the coliform indicator with outbreaks and sporadic cases of infectious hepatitis associated with the consumption of shellfish is being examined by determining the relationship of indicator levels to enteropathogenic viruses and bacteria in selected shellfish growing areas through 1) correlation of frequency of isolation of enteric viruses and Salmonella sp. to coliform, fecal coliform and ET coliform levels; 2) longitudinal survey of estuaries and shellfish for presence of human enteric viruses; 3) comparative survival of coliforms, Salmonella species, and viruses in seawater; and 4) sanitary significance of members of the coliform group. Various enteric viruses were isolated from two species of shellfish and the overlying waters in a preliminary study conducted in the Pawcatuck River, Rhode Island. A rapid plating method for enumerating coliform capable of growth at an elevated temperature (ET coliform) has been developed and evaluated at three locations.

2.0786, OCCURRENCE OF HUMAN ENTERIC VIRUSES IN WATERS AND SHELLFISH
O.C. LIU, U.S. Dept. of Hlth. Ed. & Wel., P.H.S. Environ. Health Service, *Narragansett, Rhode Island* 02882

Outbreaks of infectious hepatitis associated with drinking water and shellfish are well documented. Recently two waterborne outbreaks of hepatitis were reported from Wisconsin and Massachusetts respectively. The high incidence of infectious hepatitis throughout the year in this country may partially be attributable to polluted drinking water supplies from communities practicing marginal treatment. In order to identify this problem by using laboratory approach, a longitudinal survey has been initiated since 1969 monitoring the water supply of three northeastern communities for the presence of human enteric viral pollutants. It is hoped that the presence of any cultivable enteric virus in these supplies may serve as an indicator of potential pollution with the hepatitis virus. Periodically, 4-gallon samples were collected from these communities and processed as follows: (a) hydroextraction by using polyethylene glycol to reduce the sample volume to 1-gallon, and (b) to further concentrate this volume to 20 ml using the two-phase polymer separation method. The concentrates were examined in 3 tissue culture systems, primary monkey kidney, human amnion and human embryonic kidney bottles (3 oz.). To date, 3 isolates were obtained from these samples. This effort will continue in FY71 with a constant effort in improvement of the sampling and concentration methods. During the course of the limited survey, bacteriologic data and treatment practice have also been collected. The viral isolation data will be correlated with this field information.

The significance of this study, if positive, follows: (a) methods used are at least effective inasmuch as uncovering the viral pollutants under the particular conditions; (b) continued use of the water or consumption of the aquatic animals therefrom, may be potentially hazardous to public health, e.g. infectious hepatitis, idiopathic myocarditis, etc.; (c) leads for further epidemiologic follow-up of the population to determine the effects, if any, on those being exposed to such environmental hazards; and (d) to validate, or invalidate, the currently used bacteriologic standards as far as indication for viral pollution is concerned.

SUPPORTED BY U.S. Dept. of Hlth. Ed. & Wel. - P.H.S.

2.0787, OCCURRENCE OF HUMAN ENTERIC VIRUSES IN DRINKING WATER
O.C. LIU, U.S. Environ. Protection Agcy., Northeastern Water Hyg. Lab., *Narragansett, Rhode Island* 02882

The objective of this project is to conduct a longitudinal survey of raw and finished water supplies of selected communities for viral pollutants.

Accomplishment in FY-71: A preliminary survey of water supplies of several New England communities has been conducted in the past one and a half years. Samples were obtained periodically from both raw and finished water. Each sample contained 20 liters of water. Initially, the samples were treated by dialysis against polyethylene glycol flakes, followed by a two-phase polymer separation. The final volume of each sample was about 20 ml, thus constituting a 1000x concentration of viruses therein. These concentrates were passaged three times in both primary monkey kidney and human embryonic kidney tissue cultures. During this period, 93 samples were examined. Viruses were isolated from some of these samples. It should be stressed, however, that the possibility of the isolates resulting from a lab contamination cannot be ruled out at this time.

Plans for FY-72: The effort will be increased in this year. The methods used to collect samples and to concentrate virus therein will be altered. The gauze sample will be used to collect water samples, the volume of each sample will be increased to 100 gallons. The eluate from each gauze sampler will be further concentrated by using the two phase polymer separation procedure. All concentrates will be examined for virus in primary monkey kidney and human embryonic kidney tissue cultures and suckling mice. Data relating to coliform tests of the supplies and treatment practices will be concomitantly collected.

SUPPORTED BY U.S. Environ. Protect. Agency - O.O.W.P

2.0788, DEVELOPMENT OF A METHOD FOR CHRONIC TOXICITY BIOASSAY USING MARINE PLANKTONIC ALGAE
C.S. HEGRE, U.S. Dept. of the Interior, Federal Water Quality Admin., *West Kingston, Rhode Island* 02892

Objectives: To develop a method which will permit exposure of algal populations to constant low levels of test compounds, as well as monitoring of population dynamics or metabolic effects.

Procedures: 1. A suitable culture apparatus will be made and tested. 2. Normal population dynamics and optimal medium exchange rates will be determined. 3. The utility of the apparatus will be tested by determining minimal requirements for a few known nutrients.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0789, STUDY OF NITROGEN METABOLISM IN MARINE ALGAE
C.S. HEGRE, U.S. Dept. of the Interior, Federal Water Quality Admin., *West Kingston, Rhode Island* 02892

Objectives: To develop a method based on in vivo enzymatic activity which can be used as a bioassay parameter in determining the biological effects of potential pollutants.

Procedures: 1. An in vivo system for the assay of nitrite reductase activity in marine algae has been established. 2. Environmental factors which influence the expression of nitrite reductase activity will be investigated. 3. Cells preexposed to test compounds will be assayed for nitrite reductase activity. The results of such studies will be compared as indicators of biological effect with those of similar studies in which growth is measured.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0790, USE OF MARINE PLANKTONIC ORGANISMS FOR EVALUATING THE QUALITY OF MARINE AND ESTUARINE WATERS
T.E. MALONEY, U.S. Dept. of the Interior, Federal Water Quality Admin., *West Kingston, Rhode Island* 02892

This project is concerned with the development of bioassay methods and techniques, employing various species of marine phytoplankton and zooplankton, for determining the toxicity and identity of pollutants in the marine environment and for determining and predicting the short- and long-term effects of lethal and sublethal concentrations of pollutants upon planktonic organisms and other organisms in the marine environment.

The test species will include those which are ecologically important and, in the case of zooplankton, their various life stages.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0791, REARING AND SENSITIVITY STUDIES OF VARIOUS LIFE STAGES OF MARINE MACROINVERTEBRATES
G. MORRISON, U.S. Dept. of the Interior, Federal Water Quality Admin., *West Kingston, Rhode Island* 02892

The goal of this project is to determine the relative sensitivity of various stages of marine macroinvertebrates to specific materials and the evaluation of marine invertebrates as indicators of extreme levels of known toxicants over extended periods.

This work will eventually be incorporated in broader areas of research to determine the effects of these toxicants upon growth, reproduction, activity, metabolism, and the activity of hormones and enzymes.

The organisms studied to date are the first larval stages of Callinectes sapidus, Carcinus maenas, Uca pugilator (?), and Palaemonetes pugio and their reaction to various levels of copper.

SUPPORTED BY U.S. Dept. of Interior - F. Wtr. Qua. Adm.

2.0792, RADIONUCLIDES IN SAVANNAH RIVER ESTUARY AND COASTAL WATERS
C.M. PATTERSON, U.S. Atomic Energy Commission, Savannah River Plant & Labs., *Aiken, South Carolina* 29801

The objective of this program is to develop the capability to predict the fate of radionuclides in the Savannah River, its estuary and coastal waters. The distribution of selected radionuclides, primarily tritium, released by the Savannah River Plant will be studied. The wide range in radionuclides will require the use of many analytical techniques.

A facility for analyzing a wide range of tritium concentrations has been established and sampling and analysis has begun.

SUPPORTED BY U.S. Atomic Energy Commission

2.0793, FEASIBILITY STUDY OF WATER RESOURCE POLLUTANT IDENTIFICATION BY DIGITAL COMPUTER ANALYSIS OF REMOTE INFRARED SENSOR SPECTRAL INTENSITIES
B.E. GILLILAND, Clemson University, School of Engineering, *Clemson, South Carolina* 29631

This study will determine the effectiveness of a remote, multiband, solid-state, infrared sensing system as an aid in water resources management, including detection of industrial contaminants, thermal pollution surveys and surveillance, in the Piedmont area of South Carolina.

The research task of this proposal involves: 1) characterization of a representative sample of industrial pollutants in terms of their emission spectral signatures; 2) definition of a scanning infrared sensor system with appropriate optical and electronic instrumentation; 3) development of suitable algorithms for computer identification of pollutants using information obtained from the sensor array; and 4) laboratory and field testing a complete system including the correlation of the results with data obtained at the sites.

It is proposed that pollution events can be identified and monitored on-line in an essentially real-time operation. The final configuration of the system will use a small general purpose integrated circuit digital computer, plus the infrared sensing system, in an overall form that would be compatible with small commercial aircraft. This would afford federal, state and private agencies and organizations with an on-line means for monitoring municipal and industrial effluents.
